

Global Warming is unequivocal

- ❖ The recent IPCC report has clearly stated that “Warming of the climate system is unequivocal” and it is “very likely” caused by human activities.
- ❖ Moreover, most of the observed changes are now simulated by climate models over the past 50 years adding confidence to future projections.

Key issue for transportation:
What is your carbon footprint?

Climate

The atmosphere is a "global commons."
Air over one place is typically half way round the world a week later, as shown by manned balloon flights.

The atmosphere is a dumping ground for all nations for pollution of all sorts. Some lasts a long time and is shared with all. **One consequence is global warming!**

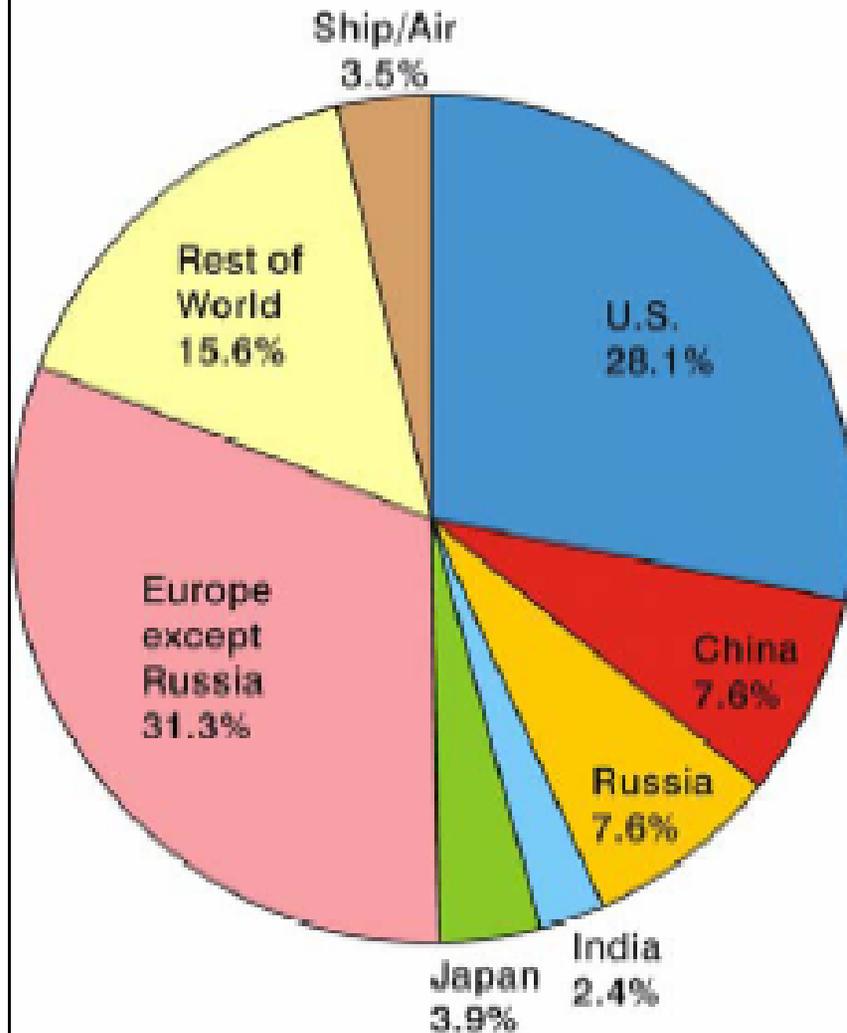

Changing atmospheric composition: CO₂

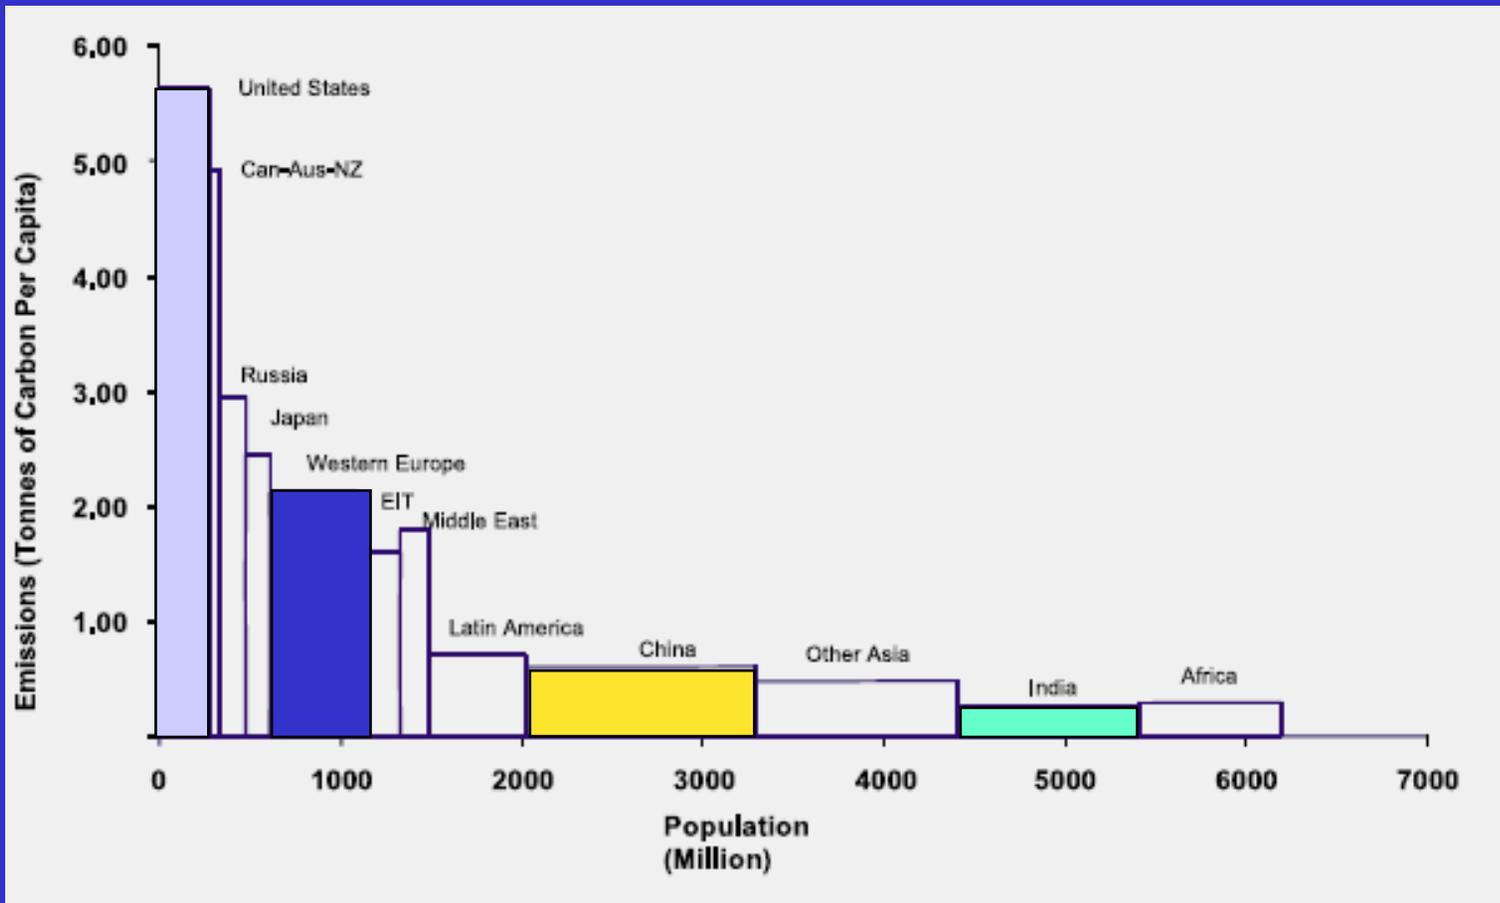

Data from Climate Monitoring and Diagnostics Lab., NOAA. Data prior to 1973 from C. Keeling, Scripps Inst. Oceanogr.

Fossil Fuel CO₂ Emissions

Accumulated Fossil Fuel CO₂ (1850-2004)

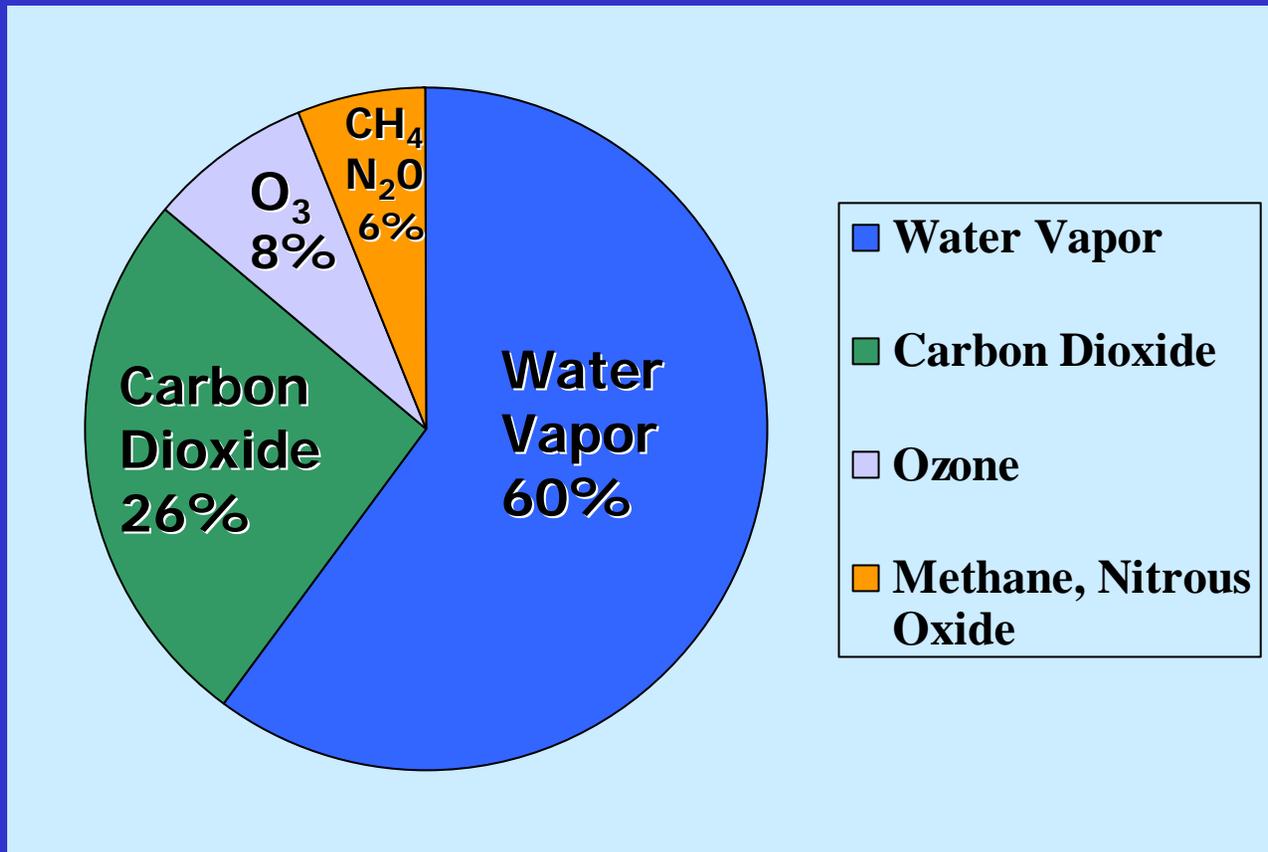

CO2 emissions in different regions in 2000 in terms of emissions per capita (height of each block); population (width of each block); and total emissions (product of population and emissions per capita = area of block).

The Natural Greenhouse Effect: clear sky

Clouds also have a greenhouse effect

Kiehl and Trenberth 1997

The Greenhouse Effect

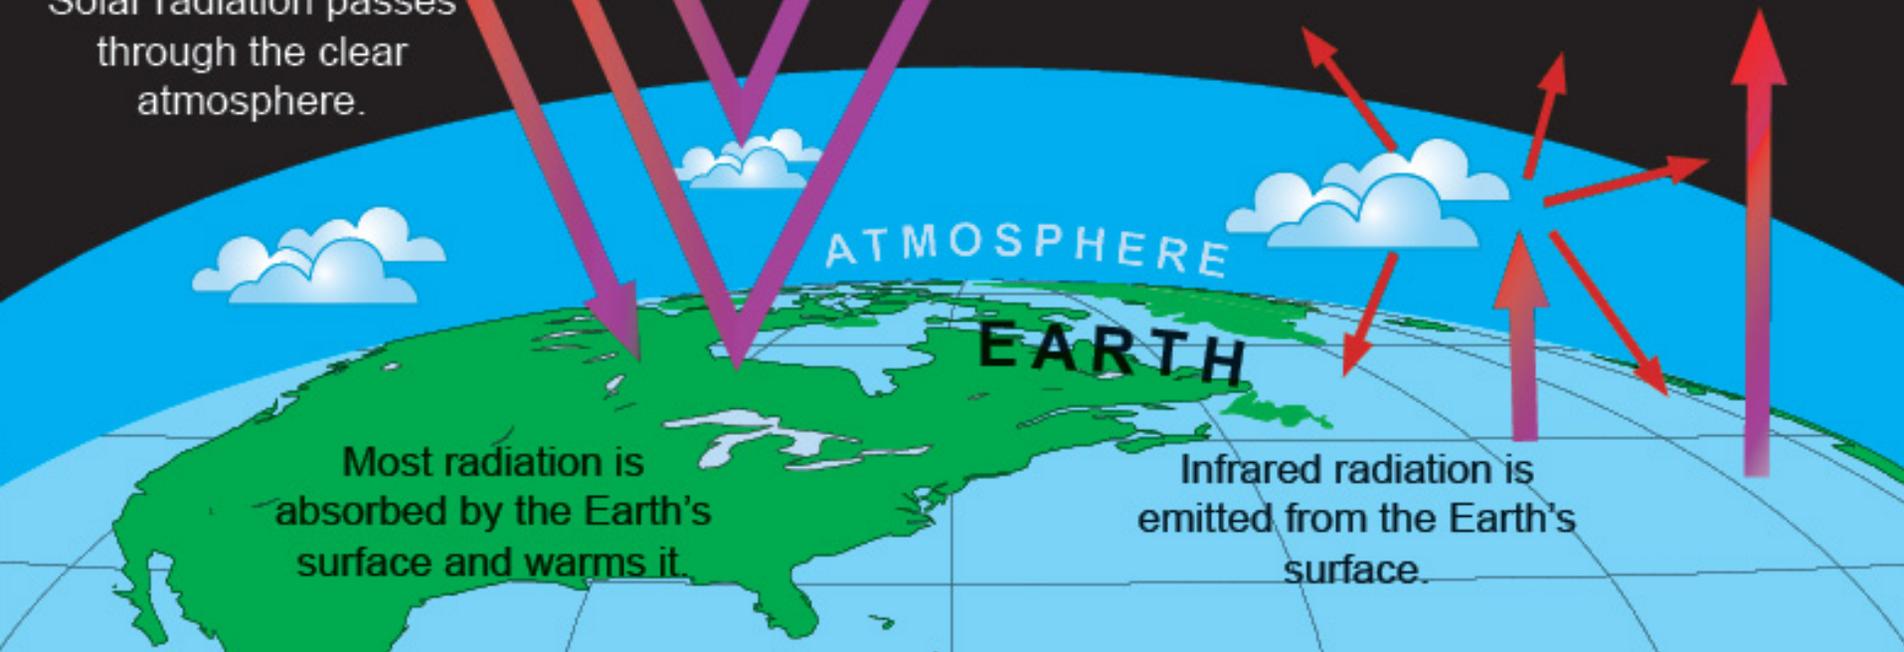

Some solar radiation is reflected by the Earth and the atmosphere.

Some of the infrared radiation passes through the atmosphere, and some is absorbed and re-emitted in all directions by greenhouse gas molecules. The effect of this is to warm the Earth's surface and the lower atmosphere.

Solar radiation passes through the clear atmosphere.

Most radiation is absorbed by the Earth's surface and warms it.

Infrared radiation is emitted from the Earth's surface.

Global Warming is unequivocal

Since 1970, rise in:

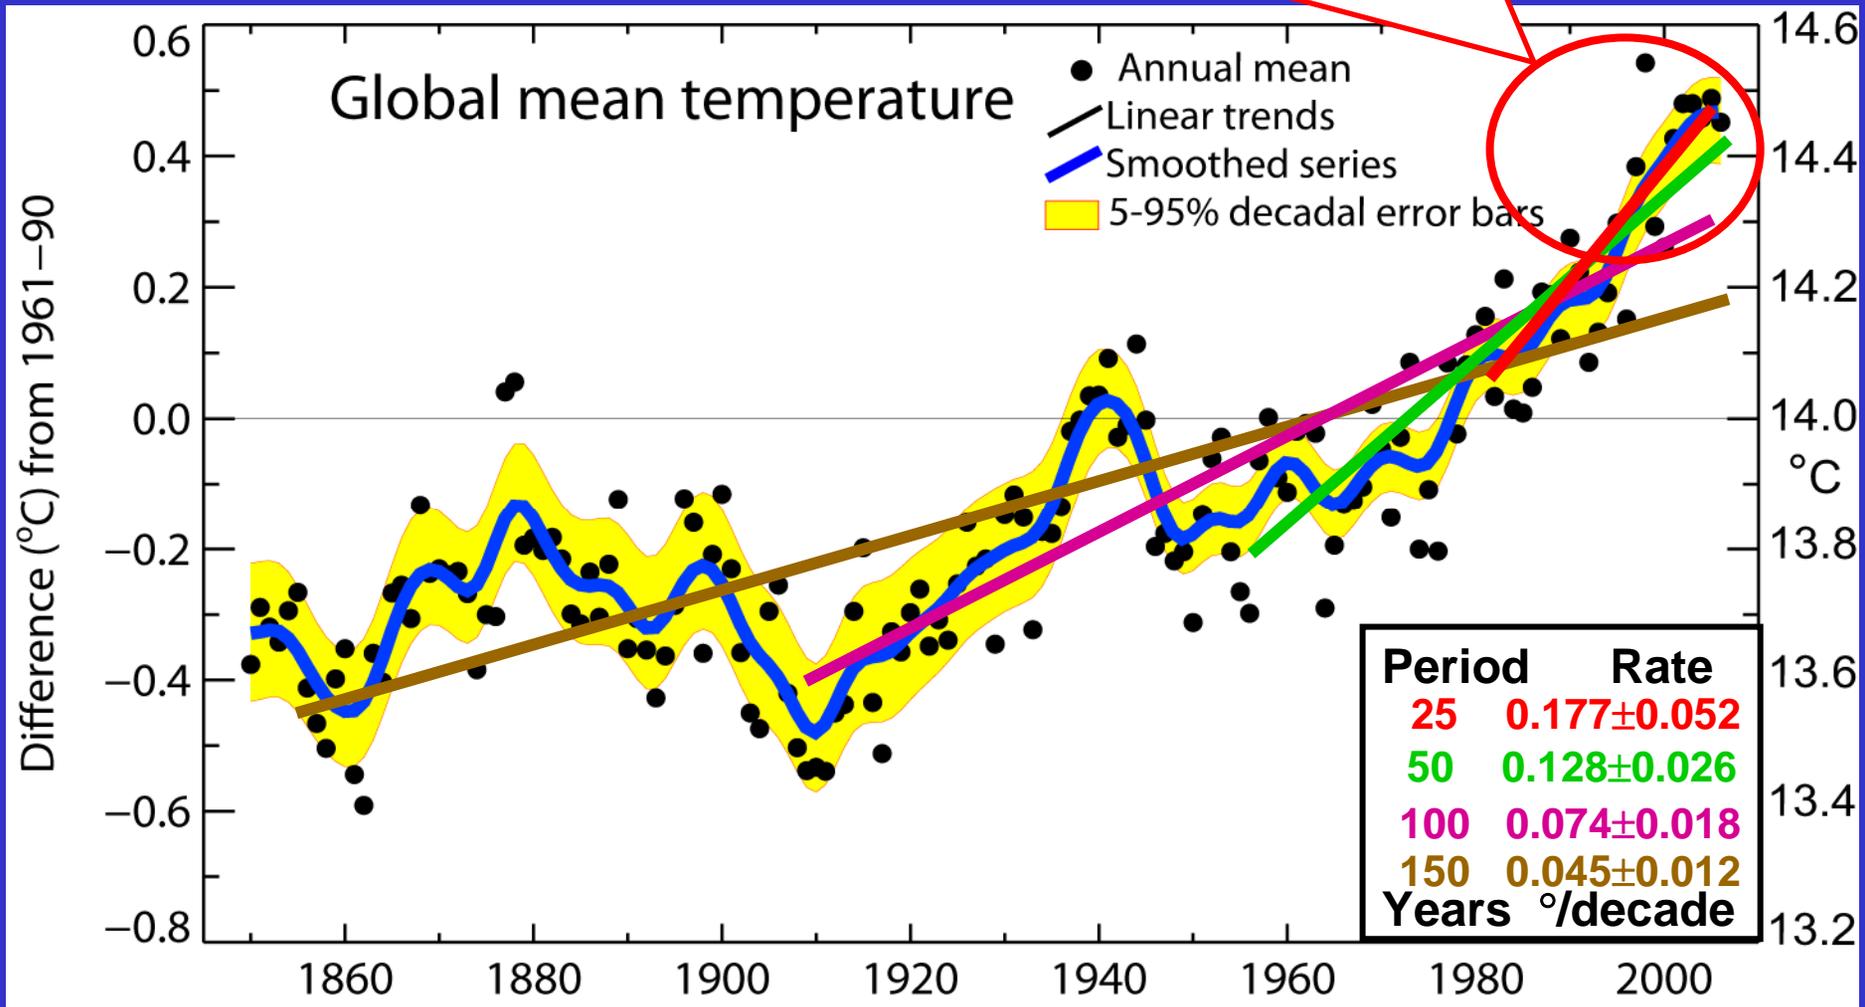

- ❖ Global surface temperatures
- ❖ Tropospheric temperatures
- ❖ Global SSTs, ocean Ts
- ❖ Global sea level
- ❖ Water vapor
- ❖ Rainfall intensity
- ❖ Precipitation extratropics
- ❖ Hurricane intensity
- ❖ Drought
- ❖ Extreme high temperatures
- ❖ Heat waves

Decrease in:

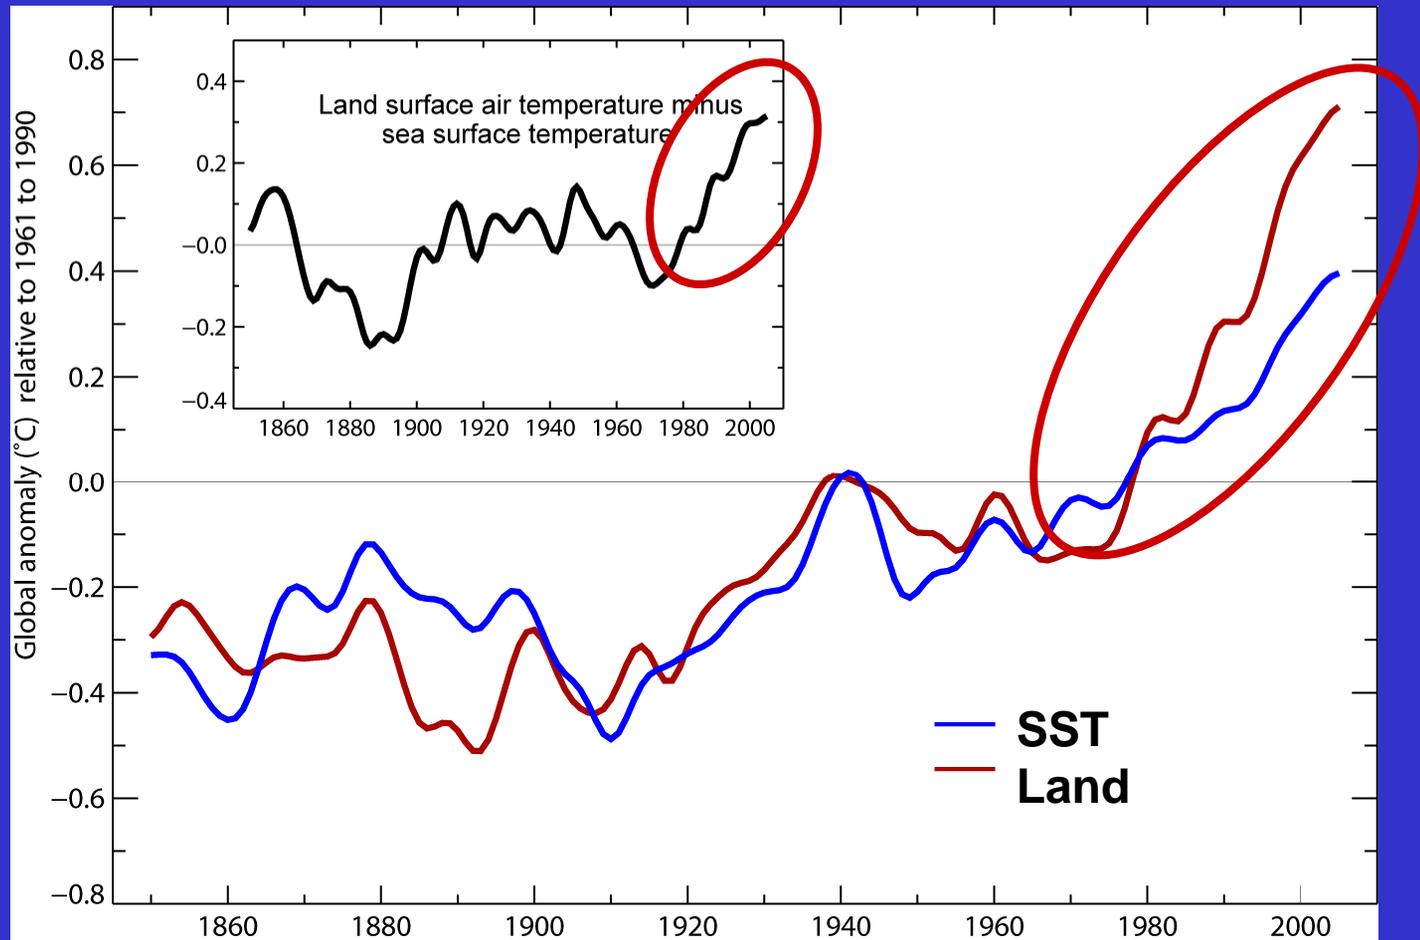

- NH Snow extent
- Arctic sea ice
- Glaciers
- Cold temperatures

Global mean temperature

Warmest 12 years:
 1998, 2005, 2003, 2002, 2004, 2006,
 2001, 1997, 1995, 1999, 1990, 2000

Land surface temperatures are rising faster than SSTs

Annual anomalies of global average SST and land surface air temperature

Controlling Heat

Human body: sweats

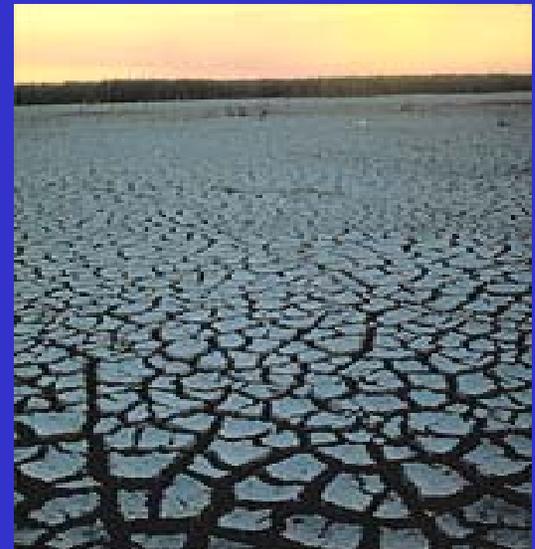

Homes: Evaporative coolers (swamp coolers)

Planet Earth: Evaporation (if moisture available)

e.g., When sun comes out after showers,

the first thing that happens is that the puddles dry up: before temperature increases.

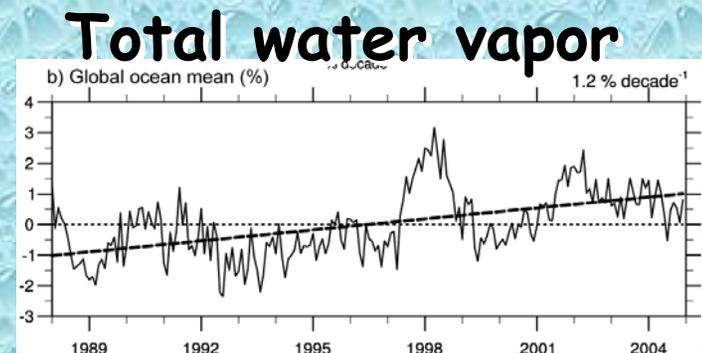

Air holds more water vapor at higher temperatures

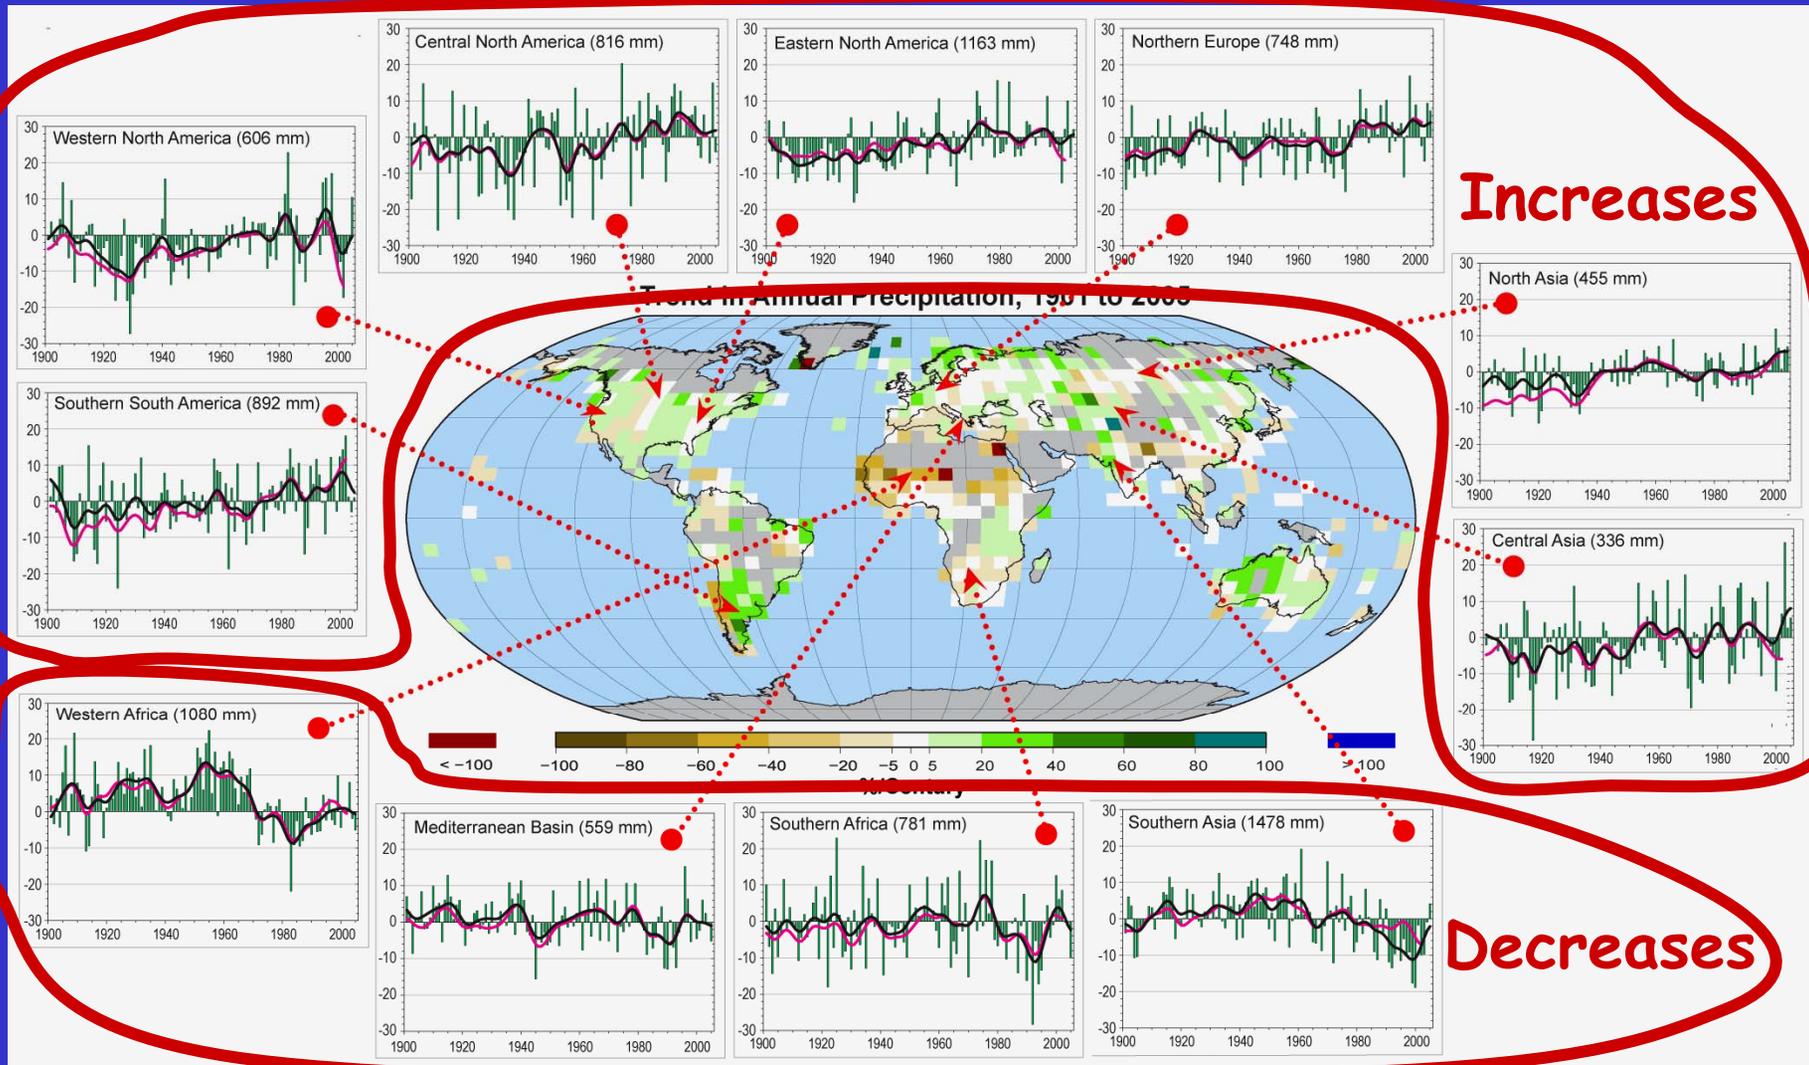

A basic physical law tells us that the water holding capacity of the atmosphere goes up at about **7% per degree Celsius increase in temperature.**

Observations show that this is happening at the surface and in lower atmosphere: 0.6°C since 1970 over global oceans and 4% more water vapor.

This means more moisture available for storms and an enhanced greenhouse effect.

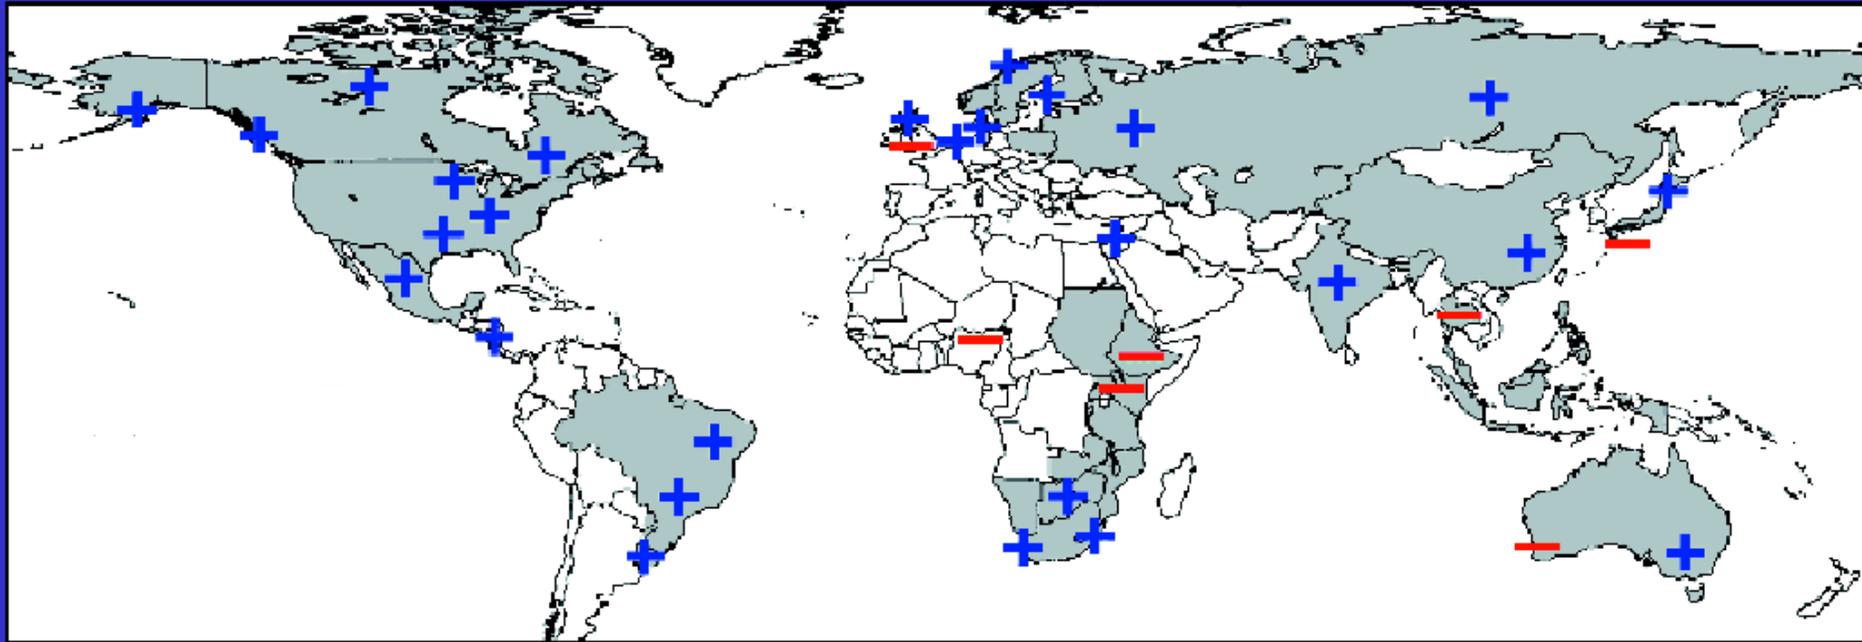

Land precipitation is changing significantly over broad areas

Smoothed annual anomalies for precipitation (%) over land from 1900 to 2005; other regions are dominated by variability.

Proportion of heavy rainfalls: increasing in most land areas

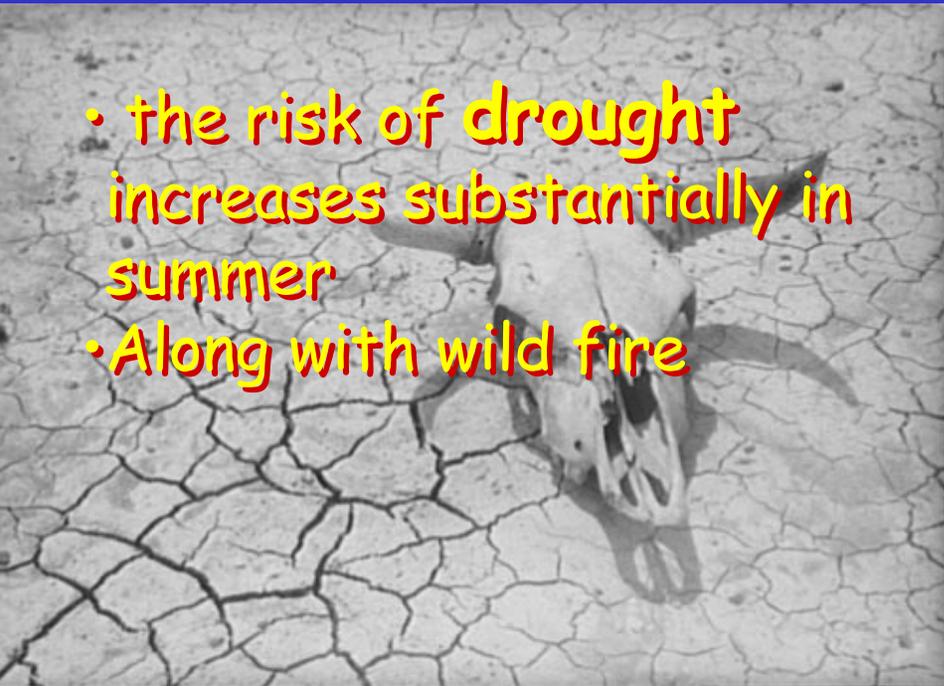

Regions of disproportionate changes in heavy (95th) and very heavy (99th) precipitation

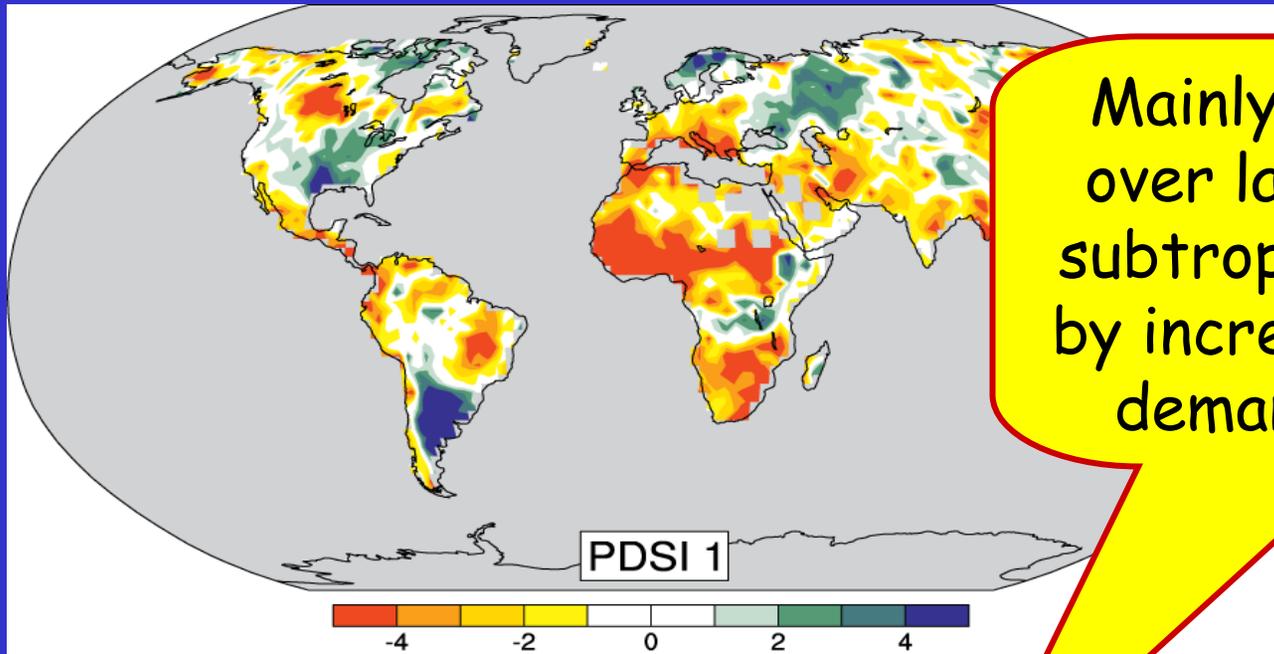

Declining Snow Pack in many mountain and continental areas contributes to drought

- more **precipitation** falls as rain rather than snow, especially in the fall and spring.
- **snow melt** occurs faster and sooner in the spring
- **snow pack** is therefore less
- **soil moisture** is less as summer arrives

- the risk of **drought** increases substantially in summer
- Along with wild fire

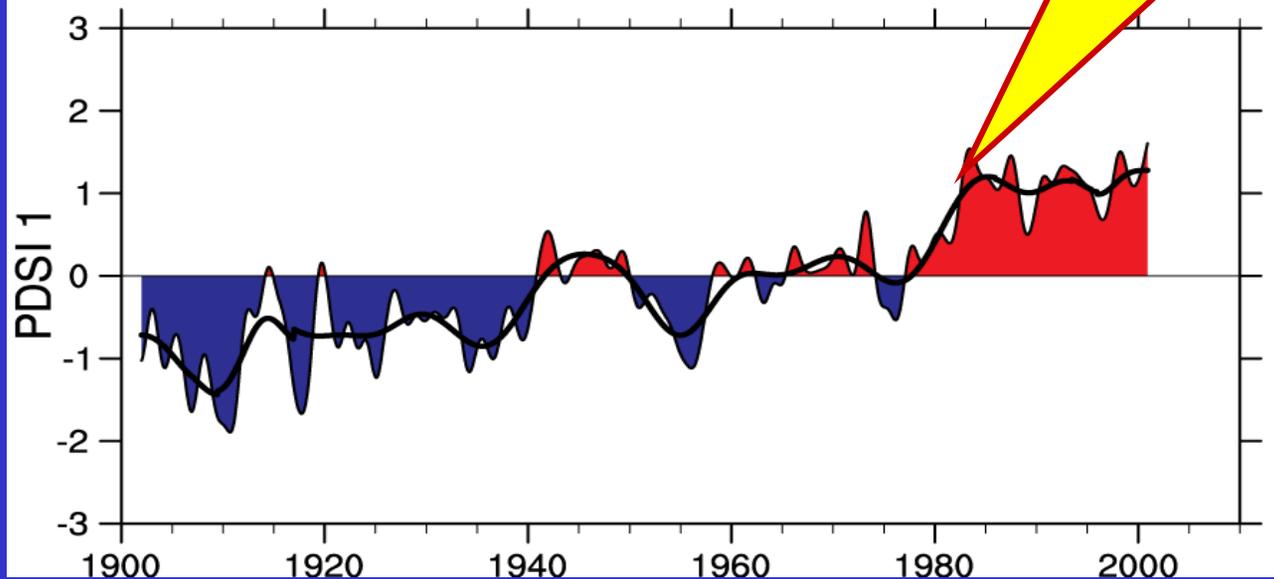

Drought is increasing most places

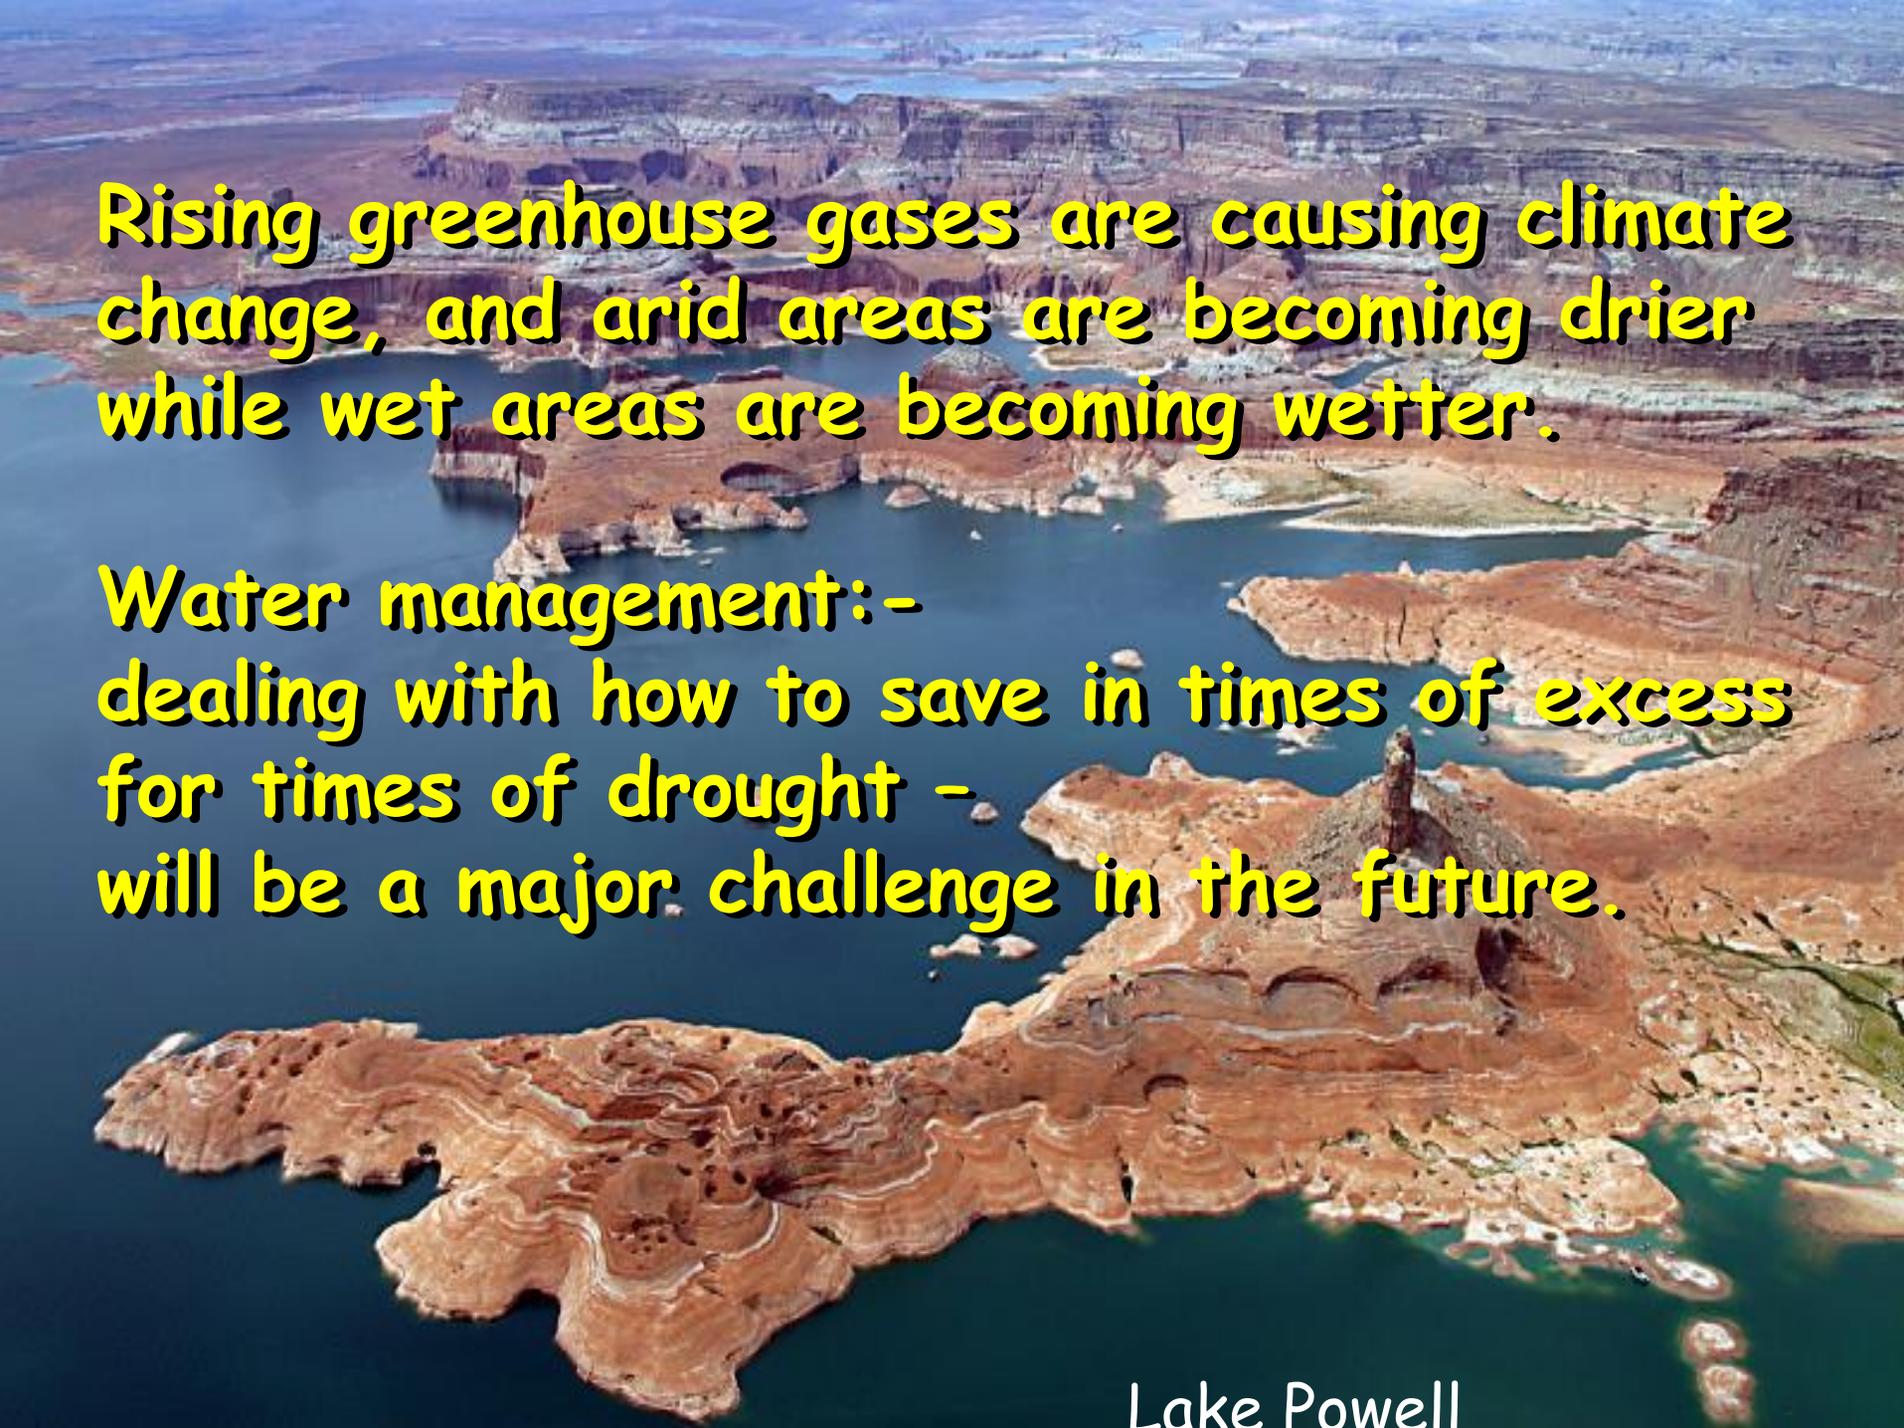

Mainly decrease in rain over land in tropics and subtropics, but enhanced by increased atmospheric demand with warming

Severity Index (PDSI) for 1900 to 2002.

The time series (below) accounts for most of the trend in PDSI.

An aerial photograph of Lake Powell, a large reservoir in a desert canyon. The water is a deep blue-green color, contrasting with the reddish-brown, layered rock formations of the canyon walls. The landscape is rugged and arid, with some sparse vegetation visible on the lower slopes.

Rising greenhouse gases are causing climate change, and arid areas are becoming drier while wet areas are becoming wetter.

**Water management:-
dealing with how to save in times of excess
for times of drought -
will be a major challenge in the future.**

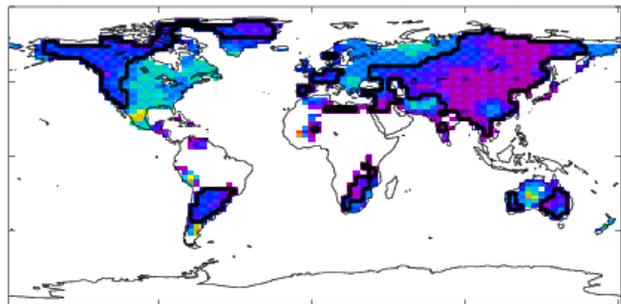

Heat waves and wild fires

Impacts on human health and mortality, economic impacts, ecosystem and wildlife impacts

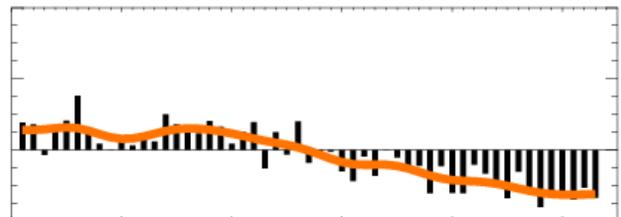

Decadal trend (days) 1951-2003

Days

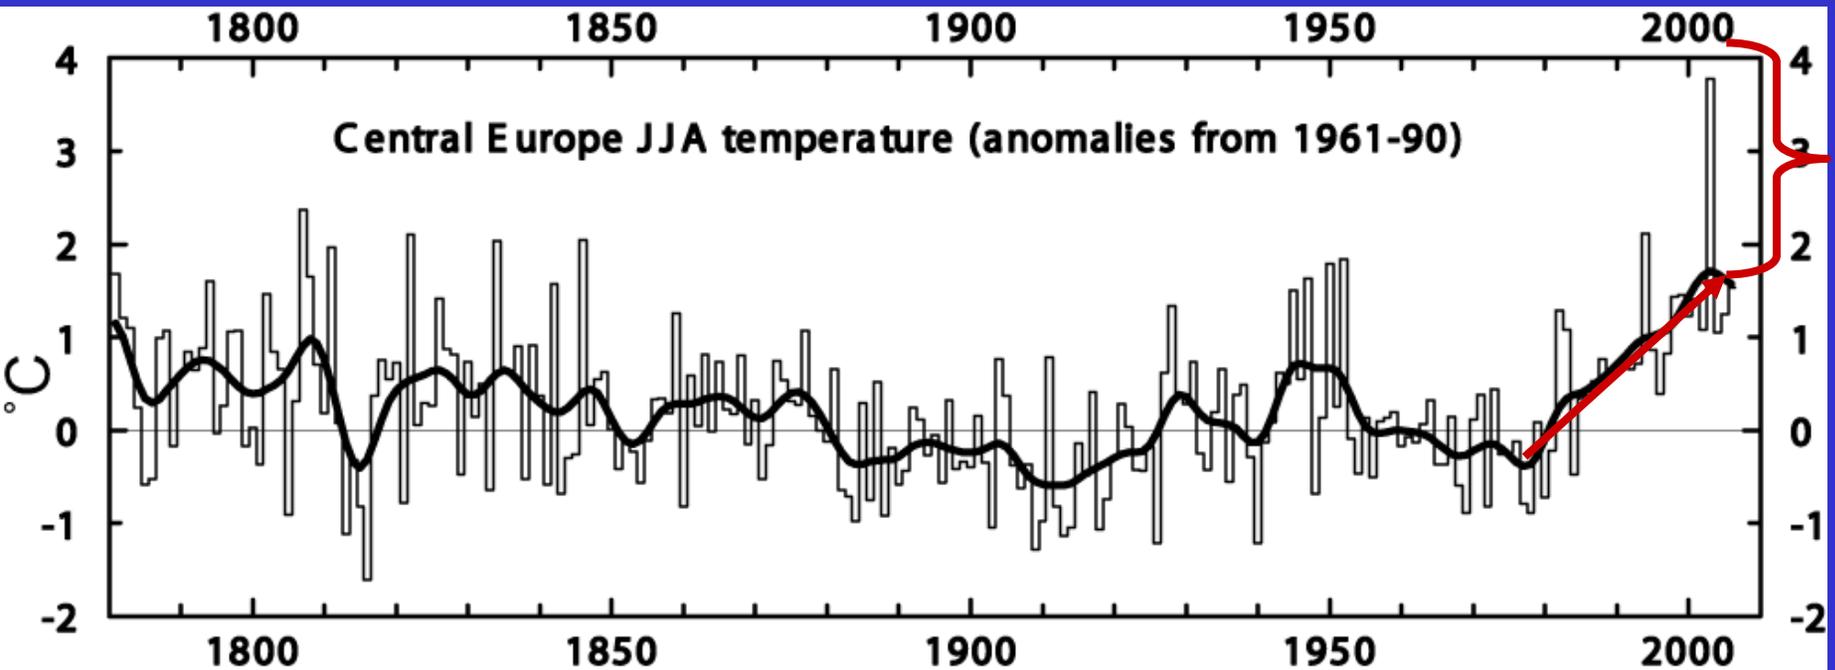

Extremes of temperature are changing!

Observed trends (days) per decade for 1951 to 2003:

5th or 95th percentiles

From Alexander et al. (2006)

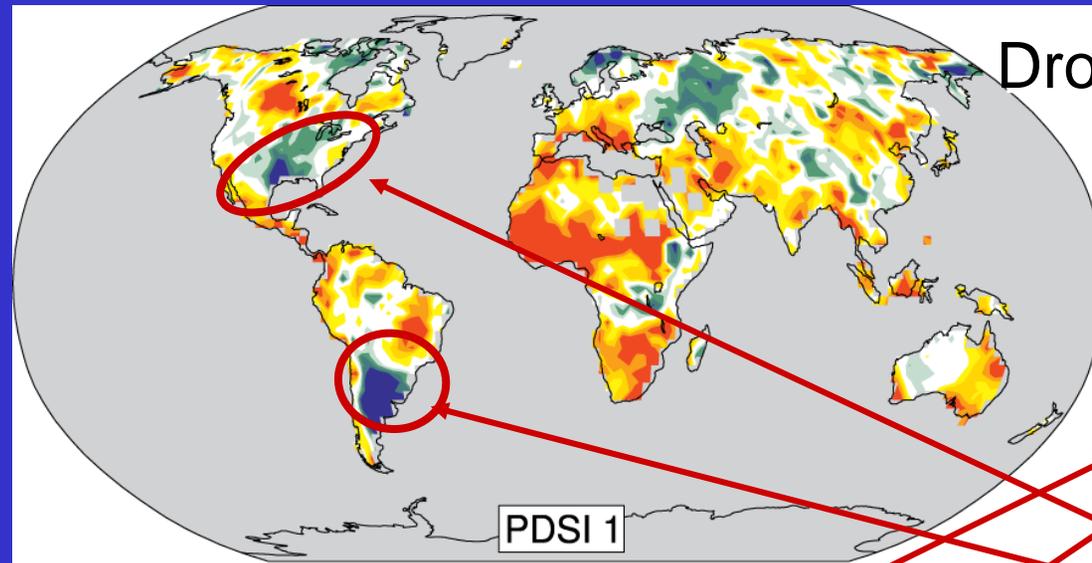

Heat waves are increasing: an example

Extreme Heat Wave
Summer 2003
Europe
30,000 deaths

Trend plus variability?

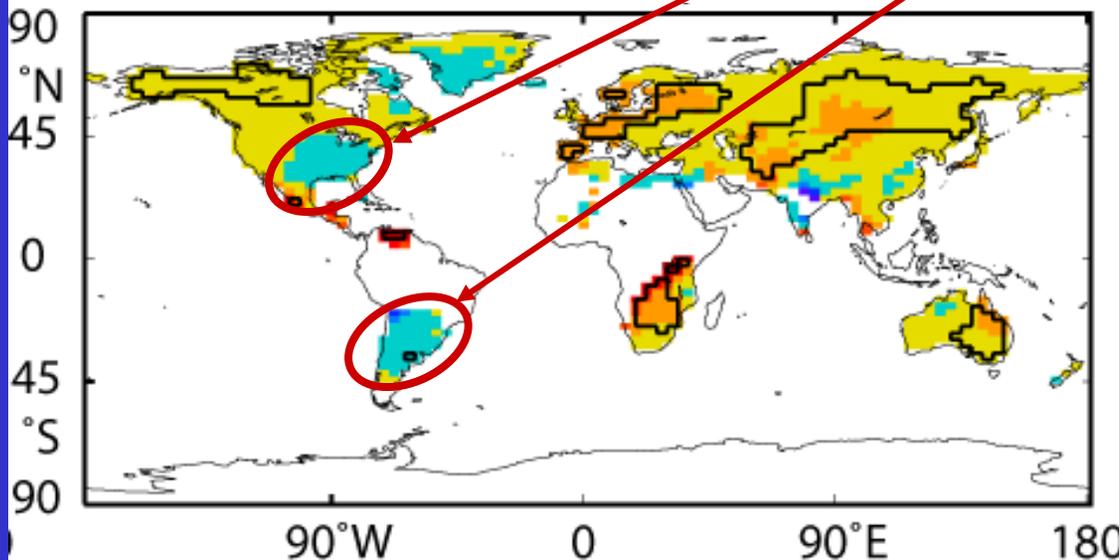

Increases in rainfall and cloud counter warming

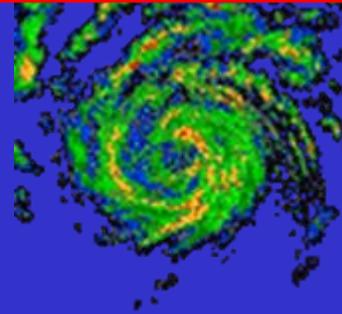

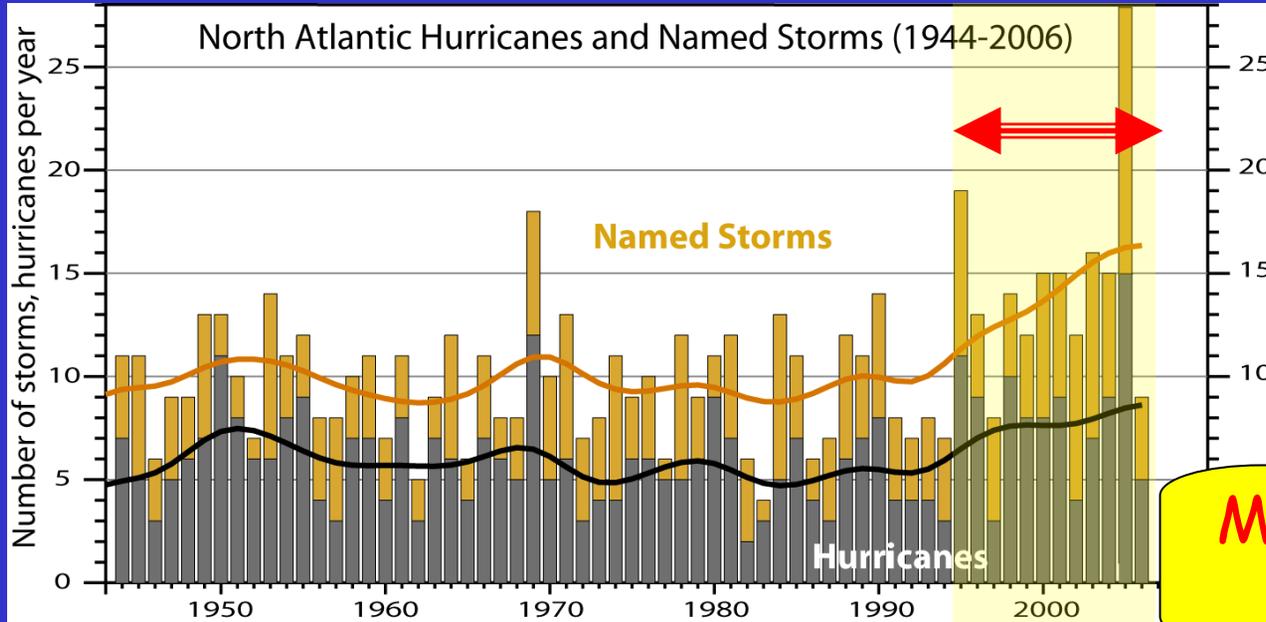

Drought

Absence of warming by day coincides with wetter and cloudier conditions

Trend in Warm Days 1951-2003

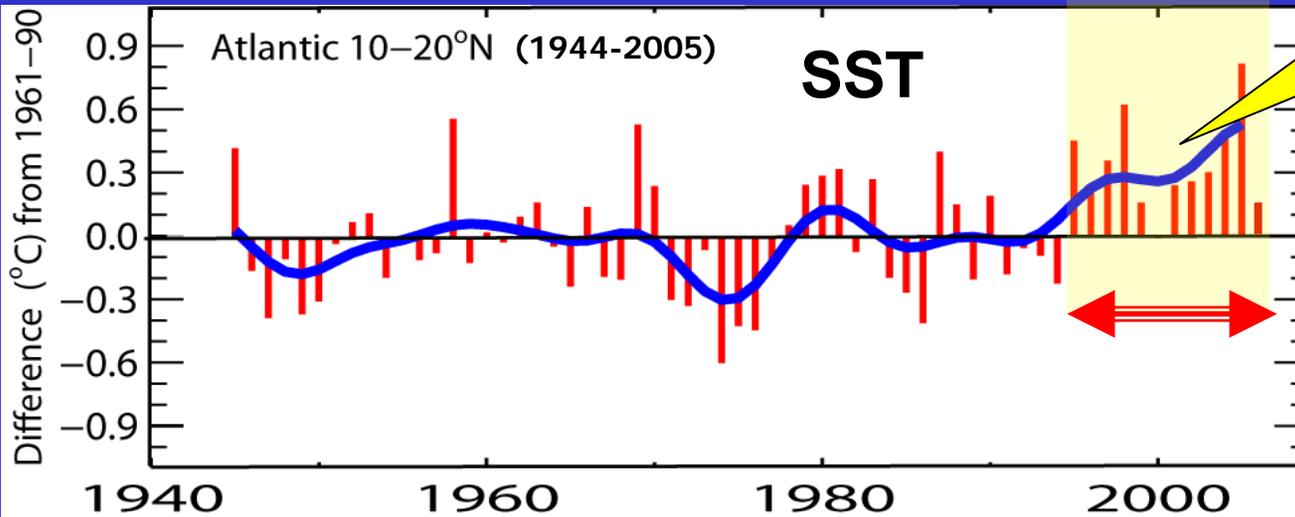

North Atlantic hurricanes have increased with SSTs

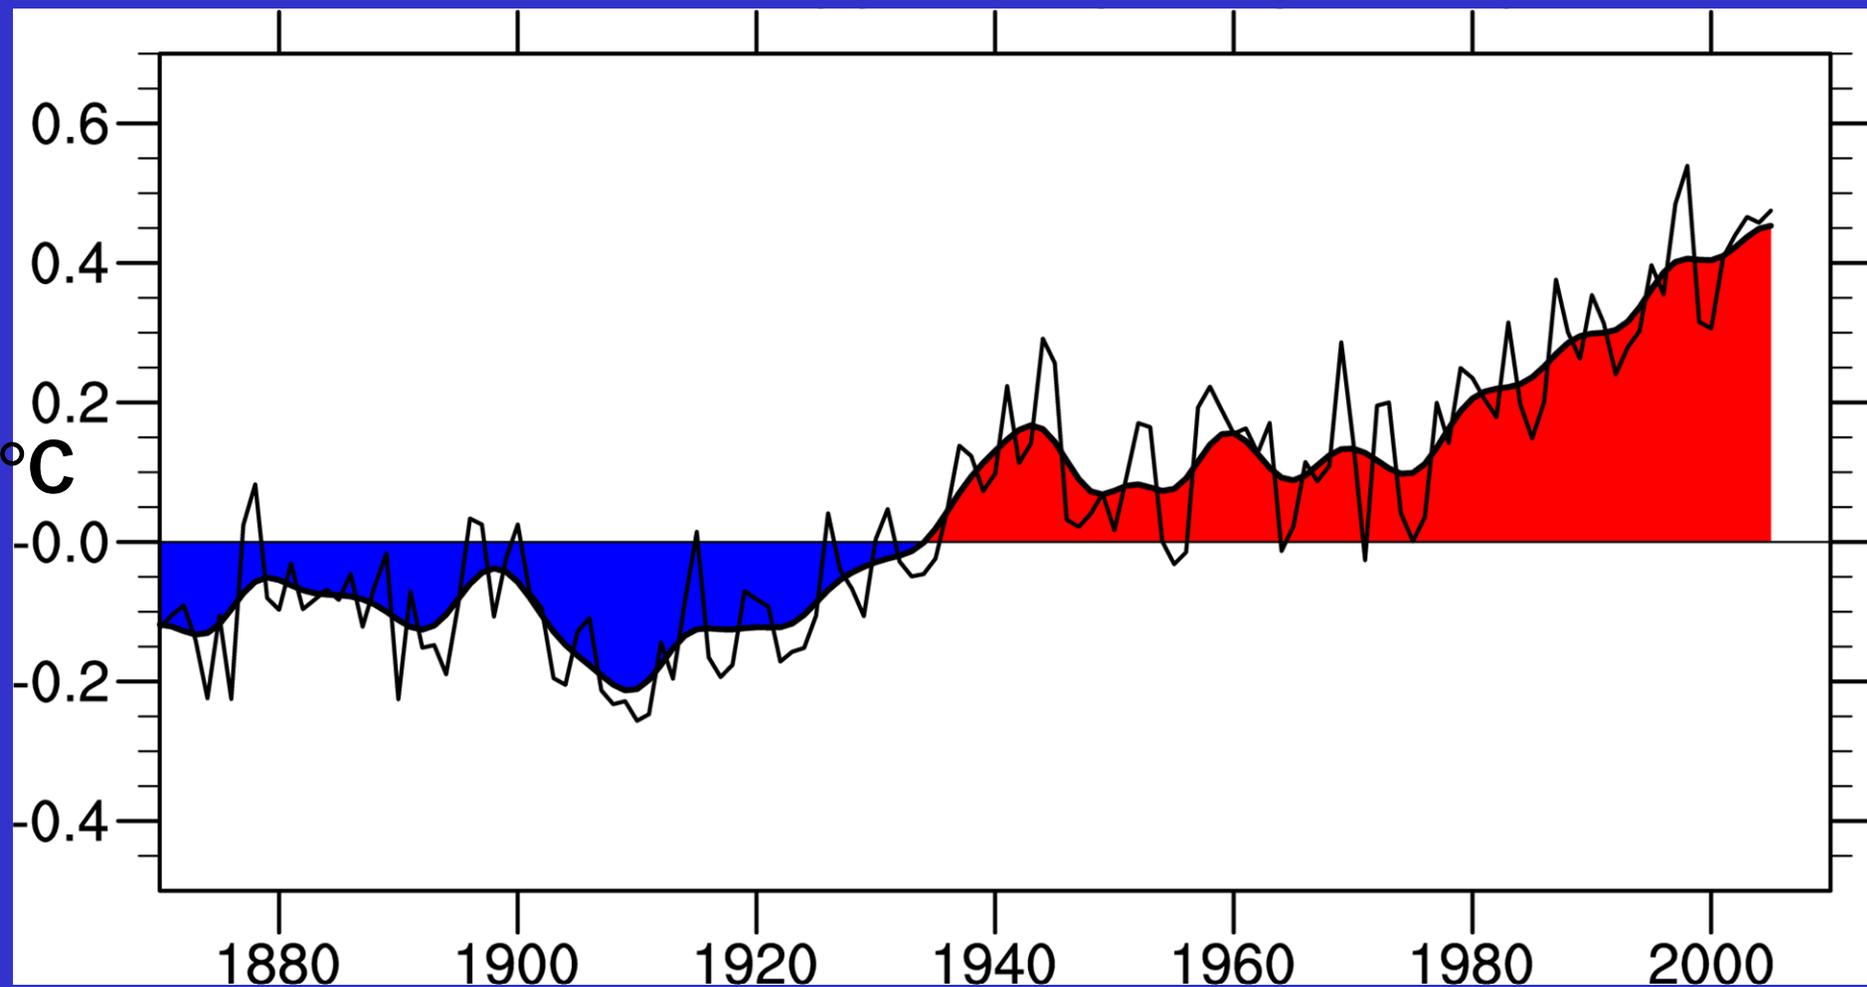

N. Atlantic hurricane record best

Marked increase after 1994

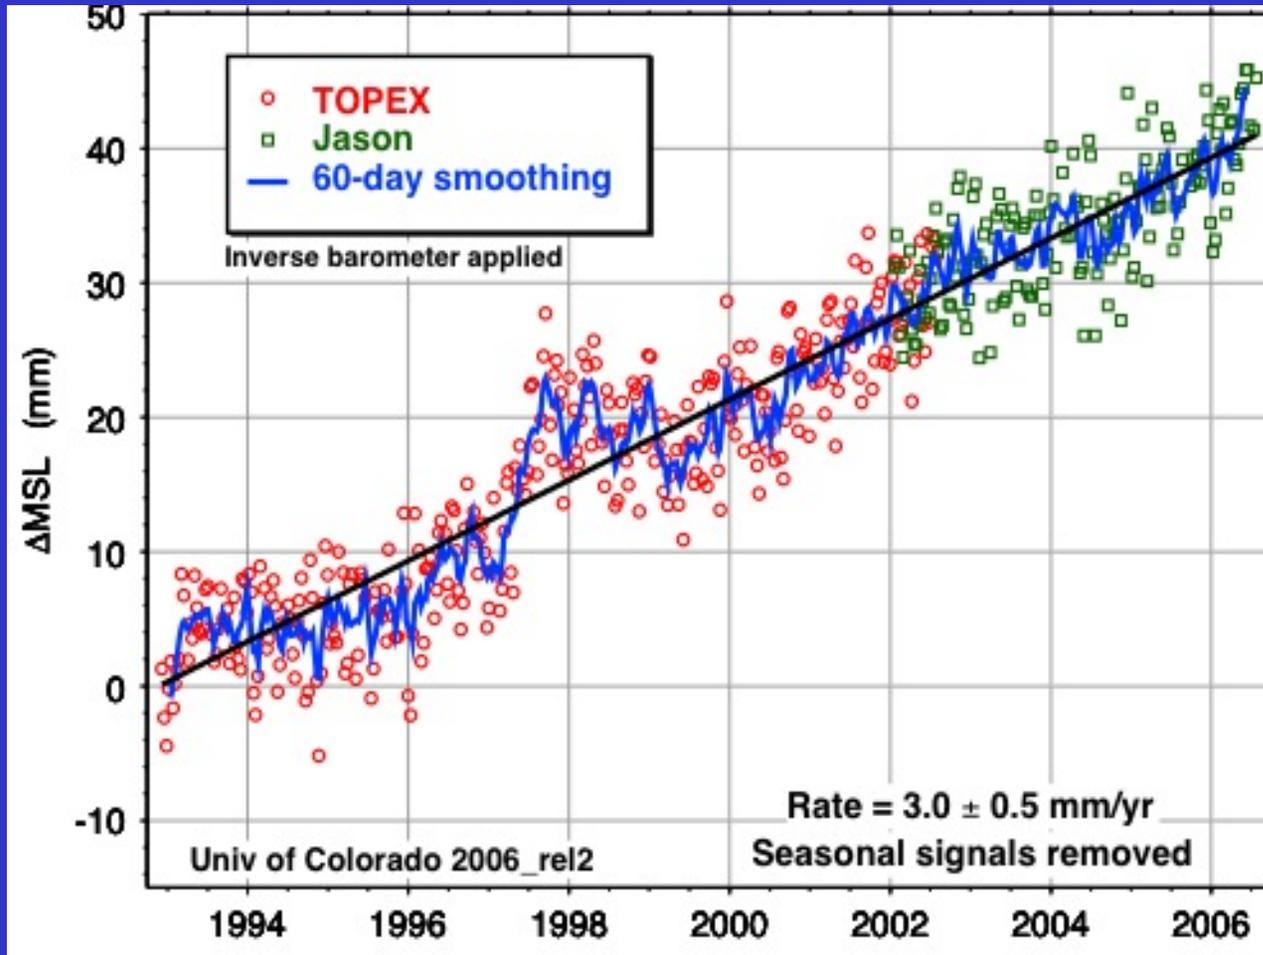

Global number and percentage of intense hurricanes is increasing

Global SSTs are increasing: base period 1901-70

Sea level is rising: from ocean expansion and melting glaciers

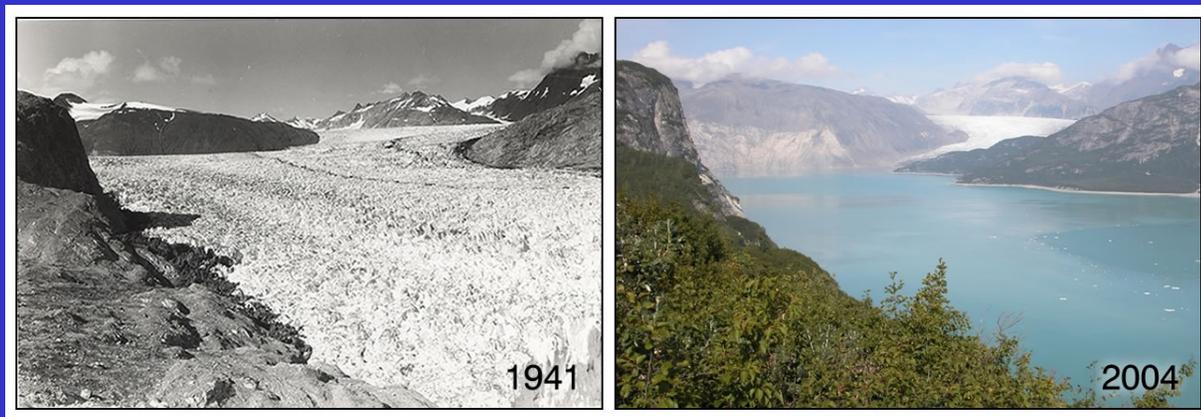

Since 1993
Global sea level
has risen 41 mm
(1.6 inches)

- 60% from expansion as ocean temperatures rise,
- 40% from melting glaciers

Evidence for reality of climate change

Glaciers melting

Modeling the Climate System

**Includes the Atmosphere,
Land, Oceans, Ice, and Biosphere**

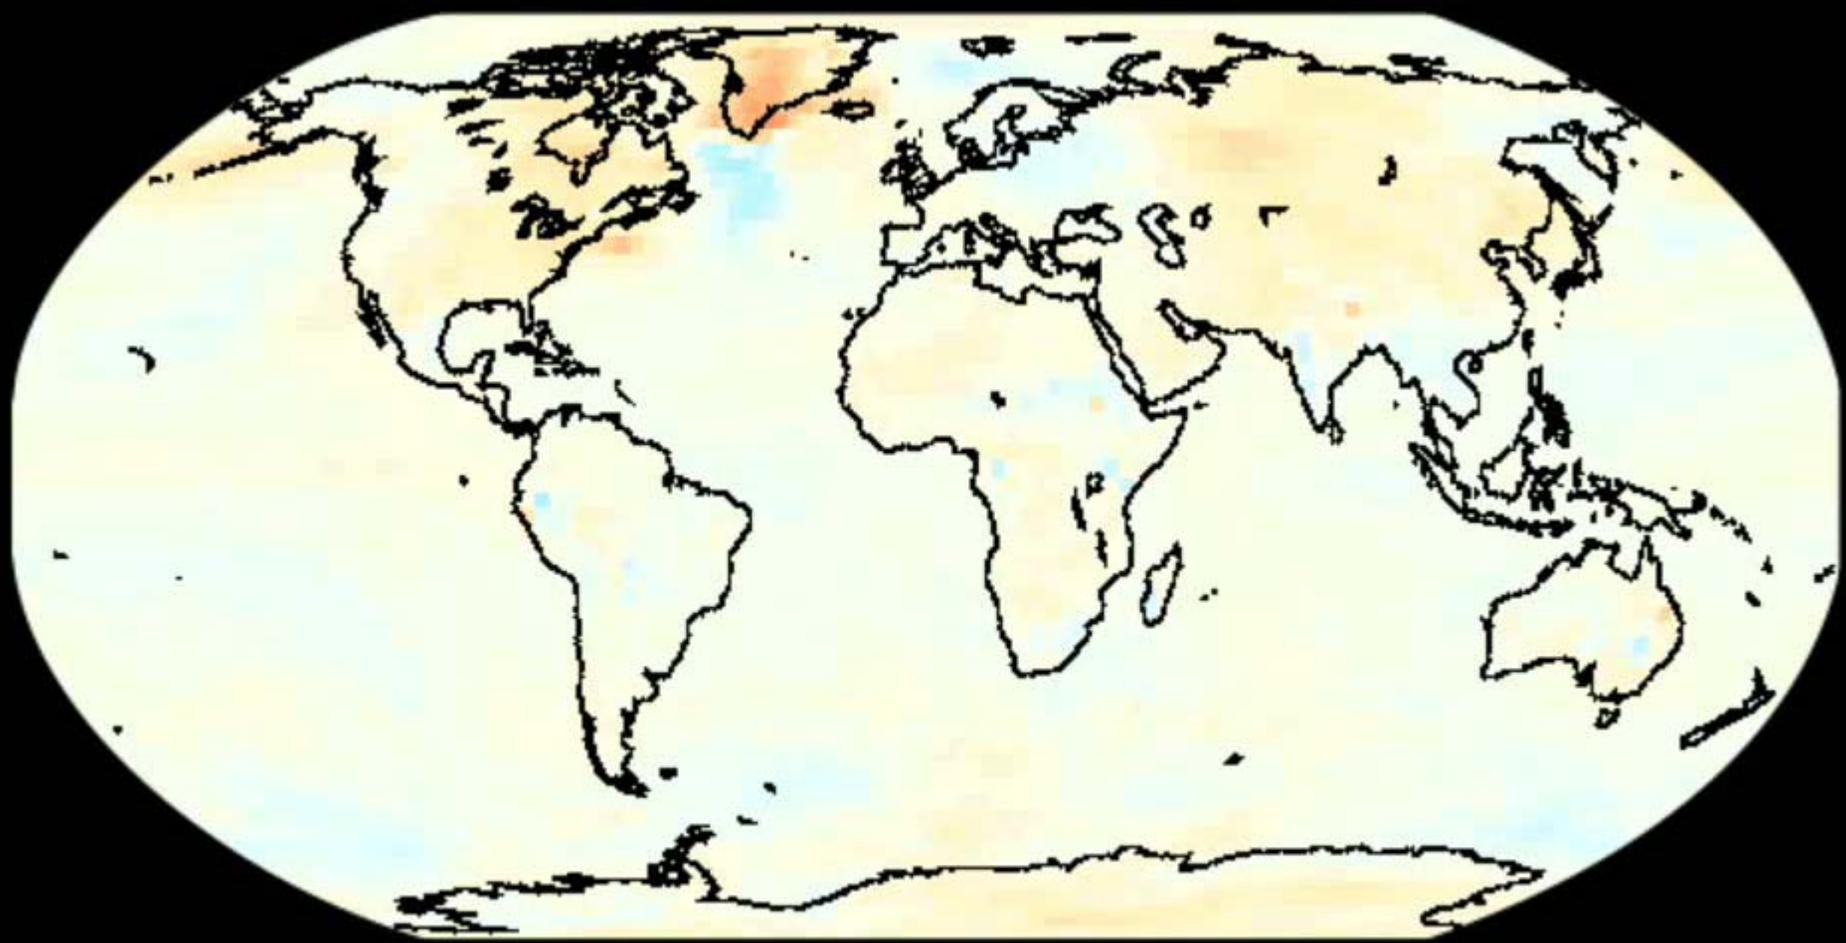

Natural forcings do not account for observed 20th century warming after 1970

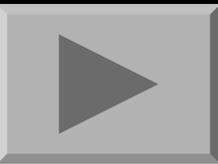

2000

Year

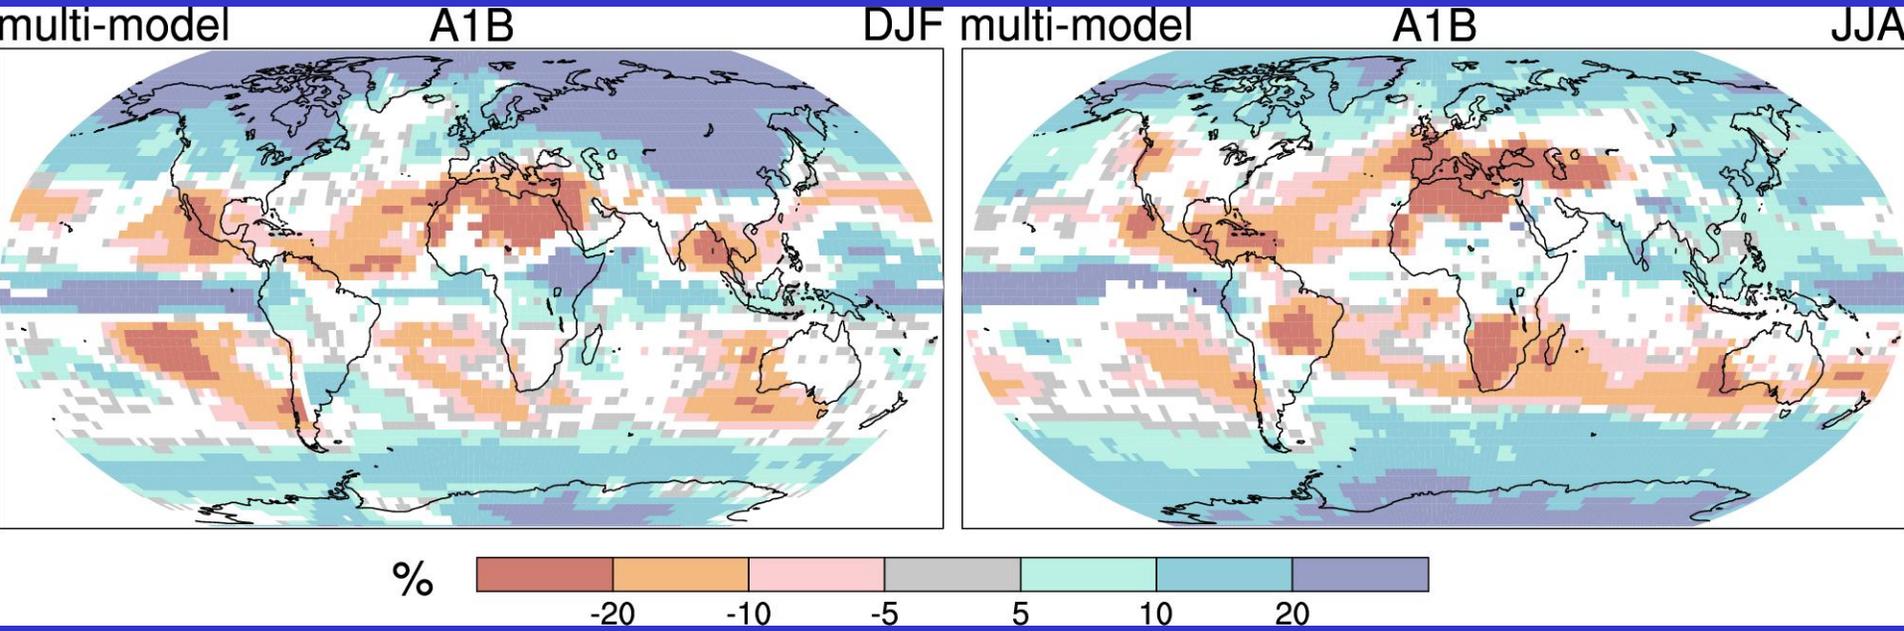

2300

Temperature Change (Celsius)

Projected Patterns of Precipitation Change 2090-2100

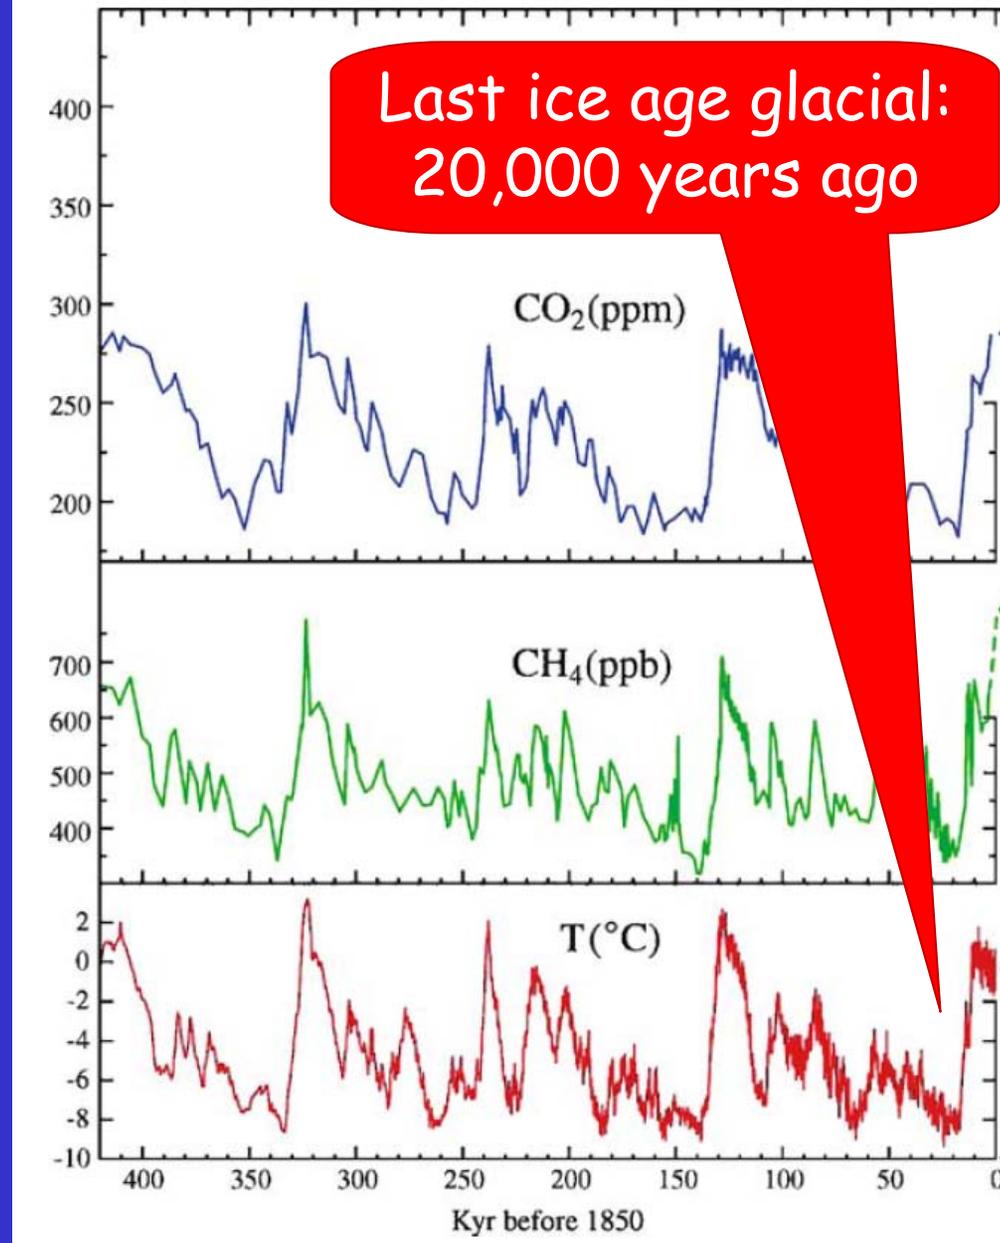

Precipitation increases very likely in high latitudes

Decreases likely in most subtropical land regions

This continues the observed patterns in recent trends

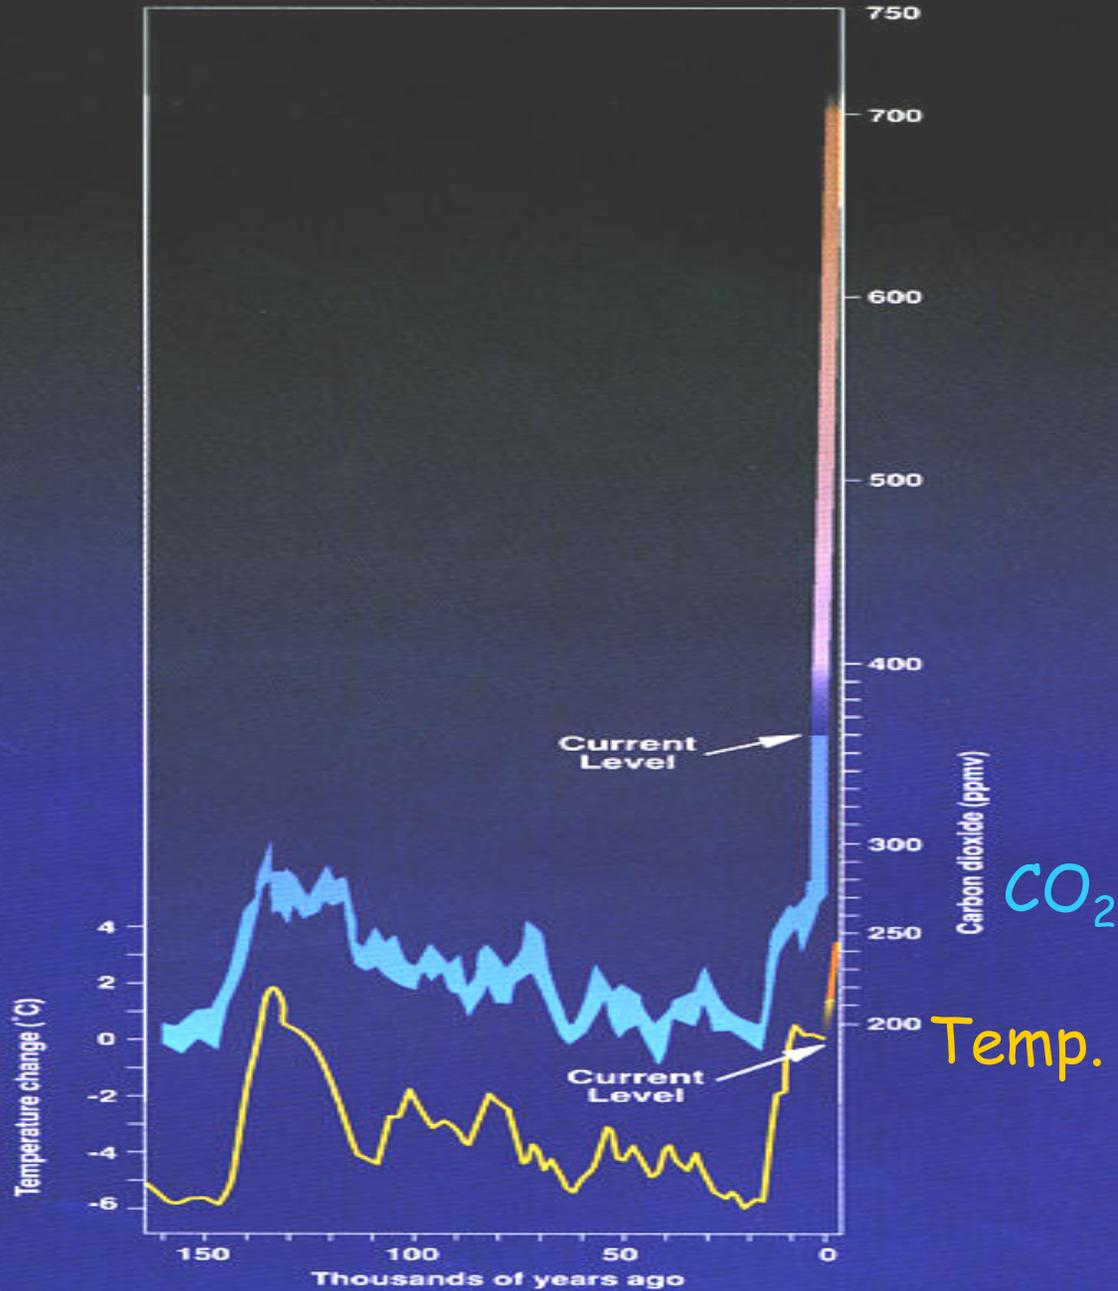

Context:

400,000 years of Antarctic ice core records of Temperatures, Carbon dioxide and Methane.

Source: Hansen, Climatic Change 2005, based on Petit, Nature 1999

Atmospheric Carbon Dioxide Concentration and Temperature Change

CO₂ concentration in the atmosphere (Antarctic Ice Core)

Temperature changes through time compared to the present temperature

The UN Framework Convention on Climate Change

- Ratified by 189 countries
- Ratified by the US
- Article 2 is statement of the objective
- Convention entered into force 21 March 1994

Kyoto Protocol

- A legal instrument under UNFCCC
- Requires net reduction in developed country averaged annual GHG emissions of 5% (US 7%) over the period 2008-12 compared to 1990 levels
- "Basket" of GHGs (CO_2 , CH_4 , N_2O , HFCs, PFCs, SF_6)
- Provisions for "flexible" market mechanisms: international trading system, credits, etc.
- 164 countries have ratified
- Protocol was ratified; took effect Feb 16, 2005.
- US withdrew in 2001. **In 2004 US emissions were 16% (20%) over 1990 levels for GHG (CO_2).**

What about a carbon tax?

Anyone can burn stuff and put Carbon Dioxide into the atmosphere as a waste product. If there was a value to Carbon Dioxide then this would presumably be reduced.

A carbon tax, carbon emission limits, or pollution fines are designed to create a **cost** for burning carbon products, like coal and oil.

Given a **target** (such as in the Kyoto Protocol) only so much can be burned and **credits** to allow burning can be **traded** (carbon emissions trading).

Such a solution can be **equitable** if implemented across the board. But it can favor those who pollute if a country does not subscribe.

Recent trends: March 2007

Coal fired power stations have been brought on line at a rate of 2 per week over the past 5 years. China leads with one every 3 days or so last years (560 new plants from 2002 to 2006 and 113 GigaWatts of coal fired power).

(200 MW each)

In the next 4 years, China is expected to bring online over 55 GW of coal fired power, but the US is right behind with 38 GW, and India with 36 GW, and the rest of the world 47 GW.

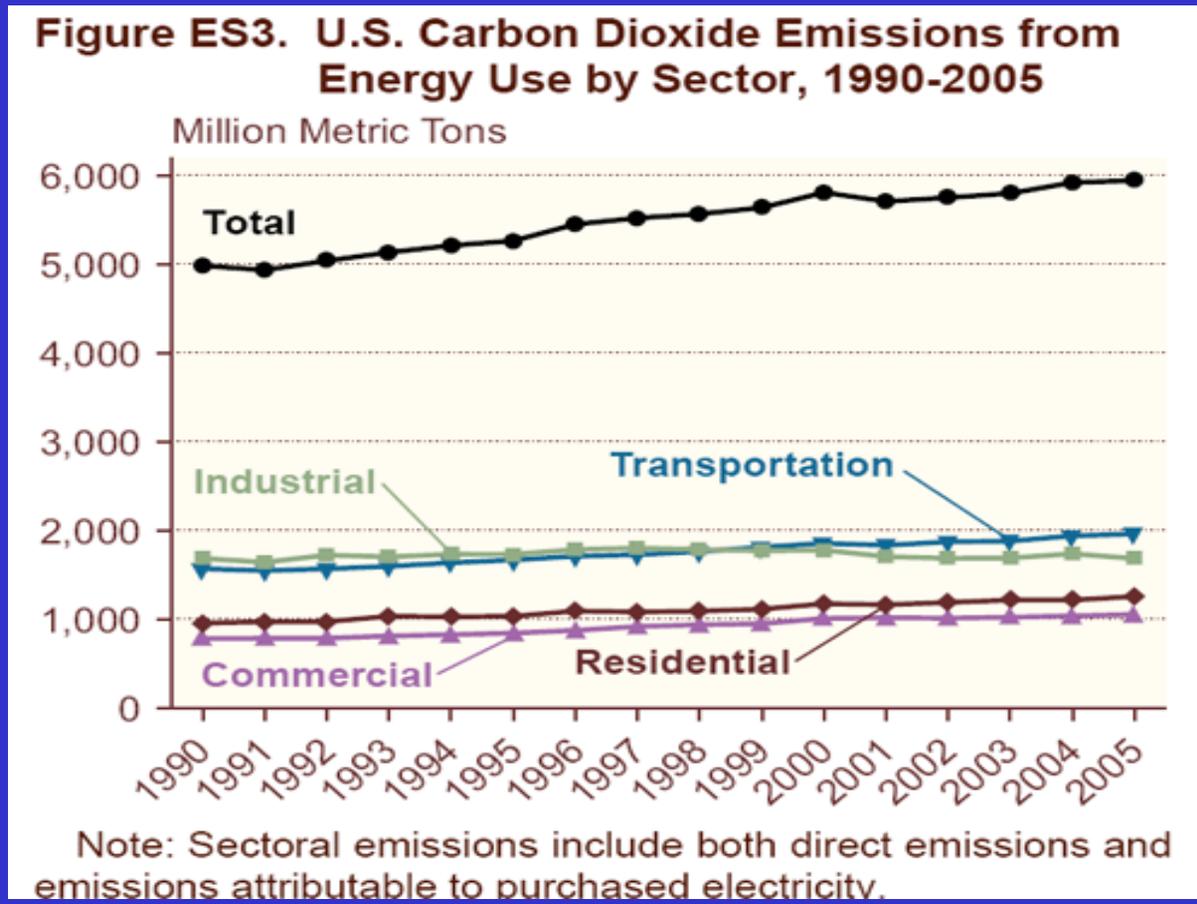

(Total 176 GW)

Far from decreasing carbon dioxide emissions, the trend is much worse than what is assumed as "business as usual".

Christian Science Monitor: March 22, 2007

Recent trends: May 2007

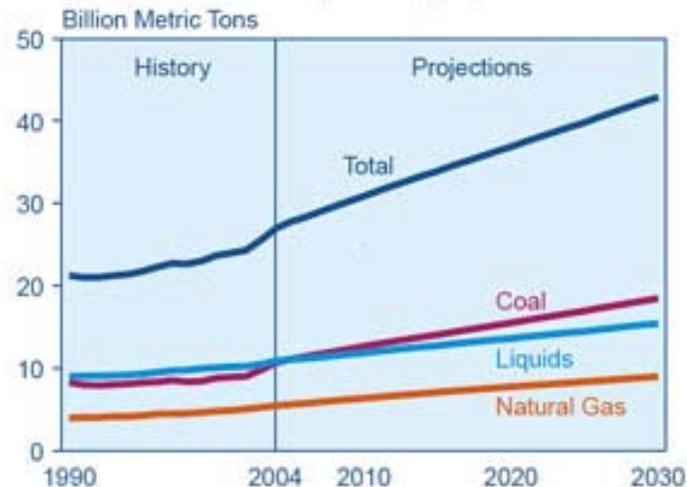

In the U.S. transportation makes up about 33% of carbon dioxide emissions (source EIA)

Recent trends: May 2007

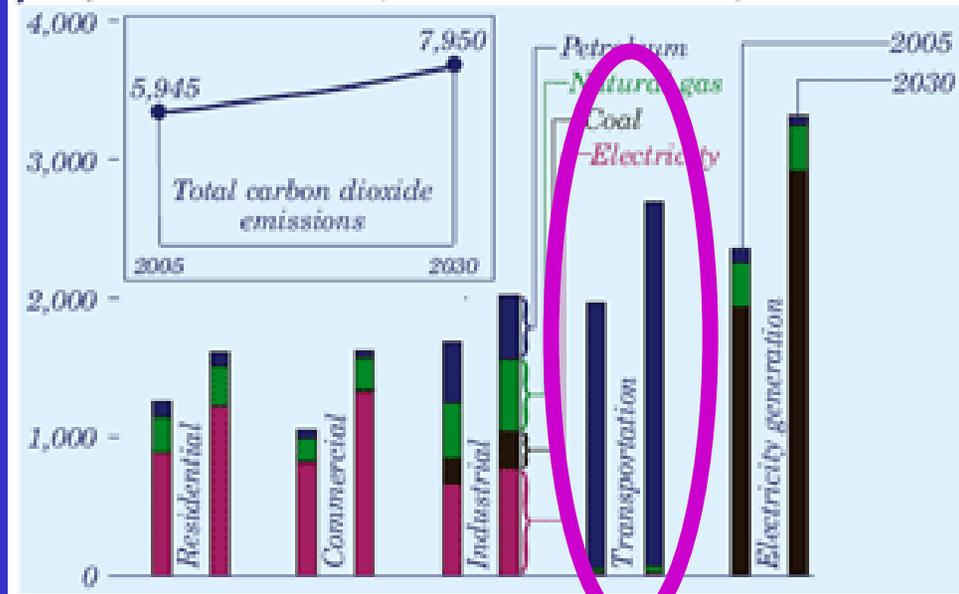

In 2030 global emissions will likely be up by 59% relative to 2004 according to the U.S. Energy Information Administration in its annual International Energy Outlook in May 2007.

Figure 78. World Energy-Related Carbon Dioxide Emissions by Fuel Type, 1990-2030

Sources: **History:** Energy Information Administration (EIA), *International Energy Annual 2004* (May-July 2006), web site www.eia.doe.gov/iea. **Projections:** EIA, *System for the Analysis of Global Energy Markets* (2007).

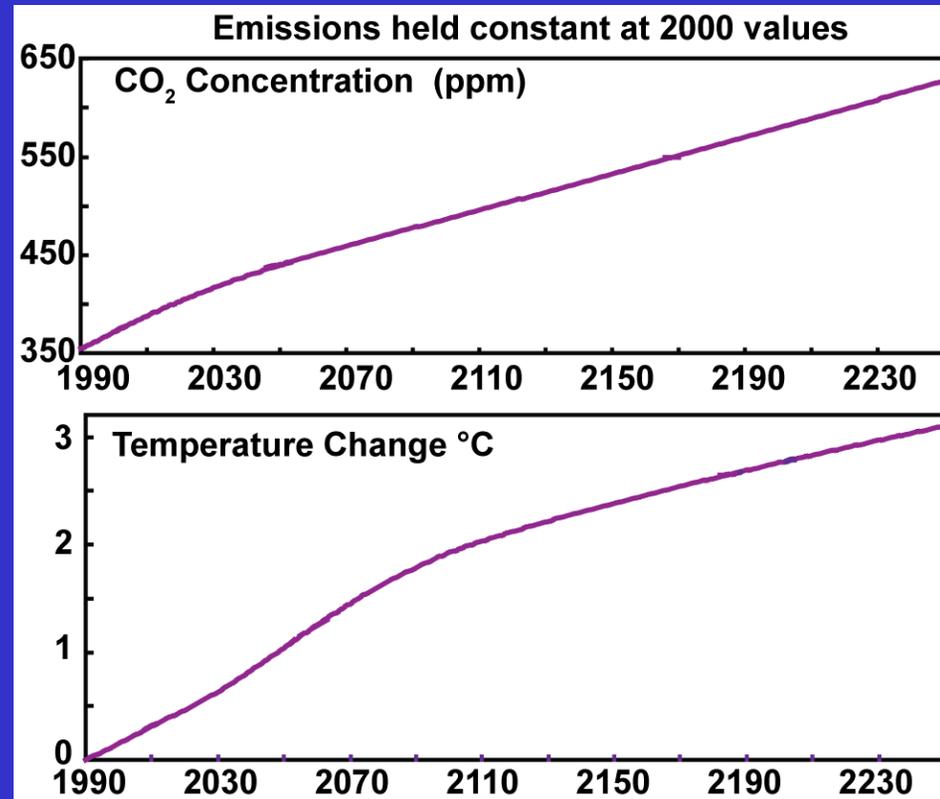

Figure 92. Carbon dioxide emissions by sector and fuel, 2005 and 2030 (million metric tons)

Global Warming

The Kyoto Protocol basically calls for a freeze on emissions to 1990 levels for developed countries. Similarly, the Montreal Protocol for ozone depletion initially called for a freeze on CFC emissions and only later was this changed to a phase out.

A freeze on emissions means that concentrations of carbon dioxide continue to increase. Climate continues to change, temperatures rise and sea level continues to rise.

Global Warming

We can slow global warming down!

Disruption arises more
from rapid change than from the climate per se.

Mitigation effects mainly payoff beyond 2050.

So we **must** adapt to climate change:
we will adapt, whether unplanned (disruptive untold
damage and loss of life), autonomously, or planned.

3 Key questions:

1. How would you or your activity respond to a carbon tax?
2. How can you reduce your carbon footprint?
3. How can you be part of the solution, not part of the problem?
